HOLLOWAY ELECTRICITY COMPANY (LIMITED).—The statutory return of this Company, made up to November 8th, has been filed. Out of a capital of £2,000 in £10 shares, only seven shares have been taken up ; no calls have been made. The original signatories to the Memorandum of Association are the only shareholders.

JAMES SIMPSON AND SONS (LIMITED).—An agreement, dated October 10th, between John and Samuel Simpson, of Darlaston, Staffs (called the vendors) and the above-named Company, states that the Company thereby agrees to buy the business of bolt and nut manufacturers, mechanical and electrical engineers, &c., carried on by the vendors, for £24,942, to be satisfied by the allotment to the vendors of 1,000 fully paid shares of £10 each, and £14,942 by payment of debts of the vendors to that extent.

JULIUS SAX AND CO. (LIMITED).—An agreement, dated November 14th, between this Company of the one part and Alfred L. Sax and Charles W. Sax (called the vendors) of the other part, states that whereas, by a former agreement between the vendors and the Company, it was agreed that the vendors should sell to the Company the business carried on by them at Ridgmount-street, Smithfield Market, and elsewhere, in consideration for £19,930, the present agreement provides for the allotment of 2,000 shares of £10 each to the vendors in full satisfaction of their claim.

CITY NOTES, &c.

CALLS DUE.—*December 30th.* ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED), £1 (final) on 45,000 £5 shares.

CASSEL'S GOLD EXTRACTING COMPANY (LIMITED).—A meeting of the members of this Company was held in Glasgow on Wednesday, at which a dividend of 5 per cent. was declared, making 15 per cent. for the year.

CHILI TELEPHONE COMPANY (LIMITED)—The Stock Exchange Committee have ordered the additional shares Nos. 40,001 to 44,000 to be quoted in the Official List.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended December 11th were £932, as against £815 for the corresponding period of last year, being an increase of £117. The total receipts for half-year amount to £19,739, against £17,798 in the corresponding period of 1891, being an increase of £1,941.

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA (LIMITED)—The third annual meeting of the shareholders of this Company is to be held at the offices, Mansion House-buildings, E.C., on Monday next, at three o'clock. The meeting is called in conformity with the Articles of Association; but the data for the statement of accounts from the Company's offices in Sydney have not yet been received, and a resolution will be proposed to adjourn the meeting to await the arrival of these accounts. The statement will be made by the Australian Chairman of the Committee, who is now in London.

EASTERN TELEGRAPH COMPANY (LIMITED). — This Company announce the payment on January 13th next, of interest of 3s. per share, less income-tax, being at the rate of 6 per cent. per annum on the preference shares, for the quarter ending December 31st; and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits for the quarter ended September 30th. The transfer books will be closed from January 6th to 13th, both days inclusive. Application has been made to the Stock Exchange Committee to grant a quotation to a further issue of £94,100 Four per Cent. Mortgage Debenture Stock.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended 30th September last of 2s. 6d. per share, free of income tax, payable on 16th January next. The share register will be closed from the 7th to the 14th January, both days inclusive. The coupon on this Company's Five per Cent. Australian Government Subsidy Debentures, due on the 1st January next, will be paid on and after the 2nd proximo, at Messrs. Barclay, Bevan and Co's. Bank, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—The Electric and General Investment Company (Limited) invite applications from existing shareholders, at par, for an issue of £100,000 Second Mortgage Debentures to bearer of the Electric Construction Corporation (Limited), bearing interest at the rate of 6 per cent. per annum; redeemable by half-yearly drawings, and entitling the subscriber of each debenture, by way of bonus, to an Income Bond of corresponding amount, payable: £1 on the 19th inst., £3 on January 16th next, £3 on March 15th, and £3 on May 15th. These debentures are to rank next after the existing First Mortgage Debentures of £150,000 as a charge upon the whole undertaking and property of the Corporation, present and future, and are secured by trust deed made between the Electric Construction Corporation (Limited) and the Electric and General Investment Company (Limited), the trustees. The debentures are redeemable at par by half-yearly drawings over a period of about 15 years. The Income Bond above referred to will carry interest from the date of redemption of the corresponding debenture, as regards each year, at a rate equal to the dividend declared on the ordinary shares for the preceding year, and will, in a winding-up, rank for payment next after the preference shares of the Corporation.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to grant a quotation to additional shares, Nos. 82,441 to 91,240.

FOWLER INSULATOR SYNDICATE (LIMITED).—A meeting of this Syndicate was held on Saturday last, at the offices, 5, Lime-street, E.C. The proceedings were private.

GEORGETOWN (DEMARARA) ELECTRIC LIGHTING COMPANY.— A meeting of this Company was held in September last, and the report and accounts of the Directors were duly approved by the shareholders. The *Georgetown Argus* of the 10th September contains an amusing digest of the Directors' report and accounts.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—A prospectus has been issued this week inviting applications for 8,000 shares of £5 each in the above Company, of which amount the prospectus states that nearly 2,000 have been subscribed by the Directors and their friends.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The report of the Directors of this Company was given in our last issue, and at the meeting held on Tuesday last the dividend of £5 per cent. on the called-up capital of the Company was declared. Mr. Twyerould was elected Chairman of the Company in place of Mr. William Morgan.

PANAMA CANAL SCANDALS.—In the course of the inquiry being made in Paris on the alleged malversations by the Directorate of the Panama Canal Company, Dr. Cornelius Herz, who is well known in Paris in connection with telegraphs and telephones, and who is the director of *La Lumière Électrique*, has been charged with receiving large sums as bribes. These accusations Dr. Herz alleges are without foundation.

PANULCILLO COPPER COMPANY.—A general meeting of the shareholders of this Company was held on Tuesday last under the presidency of Sir John Pender, G.C.M.G., M.P. In the course of his remarks the Chairman stated that, notwithstanding the very disappointing character of the business of the past eighteen months, he had known the Company's affairs to be in a much worse state. He did not, therefore, despair of the Company's future, but believed that the period of deficit and depression was passing away. For his part, he had seen the Company pass through its various phases of success and ill-success, and, while he might have disposed of his large interest in the Company to great advantage, he intended to keep his holding, as he had every faith in the Company's future prospects. The future possessed several features likely to increase the business of the Panulcillo Company. He pointed to the enormous quantity of copper that was likely to be required in the development of the electric light and other applications of electricity. Lord Kelvin had, in the course of some remarks at a recent gathering of scientific men, asserted that he considered copper was the most valuable metal of the day. Taking into consideration the material progress of the world, he (Sir John) considered this a most important statement from so eminent a man as Lord Kelvin. Copper was more valuable than gold, inasmuch as electricians were so much engaged in the extension of the applications of electricity not only to lighting, but to all kinds of motion, that he looked to copper as being not only the most valuable, but the most useful, and in this opinion he felt he could endorse Lord Kelvin's remarks. He would speak of what had been done in the use of copper in connection with submarine and land line systems of telegraphy, and he was convinced that, with a greater disposition than ever to use copper wire rather than iron wire, the consumption of copper must very materially increase, and in this increase the Panulcillo Company must receive considerable access of business. As a proof of his confidence in the future of the Company he still remained by far the largest proprietor.

TELEPHONE AMALGAMATION.—In reference to the matter of the amalgamation of the New Telephone Company with the National Telephone Company, *The Stat·st* of the 10th inst. contains an article setting out the terms upon which this amalgamation is to be effected. The article deals with the question from a financial standpoint, and refers in particular to a feature in the arrangement for which due allowance will have to be made by intending subscribers, namely, the fact that the City of London Corporation may have something to say with regard to the laying of the telephone wires underground in the "ways" provided by the City of London Electric Lighting Company (Limited), who do not appear to have obtained the all-necessary consent of the City authorities before putting down these extra "ways." The terms upon which the amalgamation is to be effected are set out in the circular as follows:—

"THE NEW TELEPHONE COMPANY (LIMITED).

"58, London Wall, E.C., December 10, 1892.

"DEAR SIR: You are aware of the interest (apart from his position as Chairman) the late Duke of Marlborough took in this Company, and in the system which it was one of its principal objects to promote, and the Directors are sensible of the great loss the Company has sustained by his death, at a time when the Company had only just come before the public. For some time he, in conjunction with his colleagues, had been considering the desirability of more closely allying the interests of this Company with the National Company, and on what basis this could be effected, consistently with the due carrying out of the objects and policy of this Company; but his sudden death prevented his bringing the matter to a conclusion. A continuance of the negotiations has, however, resulted in an arrangement (which has been concurred in by some of the most influential shareholders in the New Company) whereby, on transferring their shares to the National Company, the shareholders in the New Company can receive in respect of every share held by them with £4 paid, either one ordinary share of the National Company of £5 fully paid, or the sum of £5 in cash, or, at their option, 23 fully-paid ordinary shares of £5 each of the National Company for every 10 fully-paid ordinary shares in this Company. Shareholders adopting the latter option must forthwith pay up the balance remaining uncalled on their shares. I am now instructed to inform you of this arrangement, and in case you desire to avail yourself of either of these options, to request you to return to me, on or before Friday, the 23rd instant, one or other of the enclosed forms, duly signed.

"Yours faithfully, W. C. GOULD, Secretary."

In some accounts of this amalgamation it is stated that a condition which the Directors of the New Telephone Company have insisted upon is that the National Company shall take over the introduction of the twin-wire system, for which the former Company was specially started. This is, of course, a mistake, as quite three years ago the National Company adopted the twin-wire system, and set to work gradually converting their London lines into twin-wire lines. At the present time a large pro-

Hosted by Google

portion of the London Exchanges are worked on the twin-wire system. Between three and four thousand miles of these wires are already laid, and the system is being pushed forward as fast as circumstances will permit.

WOODHOUSE AND RAWSON UNITED (LIMITED).—We have been unable to obtain the report and balance-sheet issued by this Company for the year ended July 31st last; but we understand that the accounts show a loss of nearly £87,000, after taking credit for the balance brought forward from last year of £8,000 and taking £35,000 from the reserve fund.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Dec. 9, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,865.

WESTERN UNION TELEGRAPH COMPANY.—The official announcement of the usual quarterly dividend of 1¼ per cent. on stock was made on Wednesday. The earnings of the Company are about the same as for last year.

ORDER AT ONCE.

"The Electrician"

Electrical Trades' Directory

AND

HANDBOOK FOR 1893.

SPECIAL NOTICE.

"The Electrician" Directory is published earlier in the year than any similar book, and therefore intending Subscribers and Advertisers are desired to send on their orders for Subscription Copies and Advertisements **at once.**

"The Electrician" Directory is the only Electrical Directory which gives all the most Reliable and Valuable Information relating to the Electrical and Kindred Trades. Only the Latest Information is included in the Book.

New Firms and intending Subscribers and Advertisers can be supplied with printed Circulars, giving full information relating to the well-known **Blue Book,** post free on request to any part of the world. Continental firms can be supplied with Circulars in French and/or German on request.

Several New Features will be introduced in the 1893 Edition, and all the original well-known Tables and Statistics will be brought quite up to date.

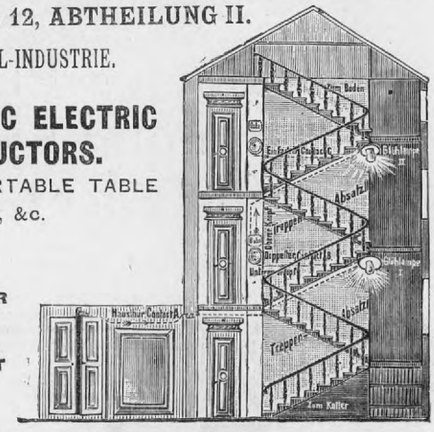
"THE ELECTRICIAN" PRINTING AND PUBLISHING CO., LTD.

F. BUTZKE & CO., BERLIN, S., RITTERSTRASSE 12, ABTHEILUNG II.

AKTIEN-GESELLSCHAFT für METALL-INDUSTRIE.

All APPARATUS and MATERIAL for INSTALLATIONS of DOMESTIC ELECTRIC SIGNALS and ALARMS, TELEPHONES, and LIGHTNING CONDUCTORS.

ELECTRIC BELLS, ANNUNCIATORS, PUSHES, TELEPHONES, MICROPHONES, PORTABLE TABLE TELEPHONES, LINE-CHANGERS, MAIN SWITCHES, SAFETY FUSES, &c., &c.



SPECIALITIES.

APPARATUS FOR AUTOMATICALLY LIGHTING STAIRCASES AT STATED TIMES, EITHER BY BATTERIES OR ACCUMULATORS.

This Apparatus should be in every Mansion.

OTTO SCHUMANN'S DOUBLE-SILVERED CONCAVE GLASS REFLECTORS for INCANDESCENT LAMPS, unequalled for Durability of Reflecting Power, Elegance, and Neatness.

COUNTY BOROUGH OF BURNLEY.

TO ELECTRICIANS AND OTHERS.

The TOWN HALL and PARKS COMMITTEE of the BURNLEY TOWN COUNCIL invite TENDERS for the SUPPLY and FIXING of FITTINGS for the ELECTRIC LIGHTING of the interior of the Town Hall.

Drawings may be seen, and specifications, bills of quantities, and forms of Tender may be obtained at the Office of the undersigned, upon payment of one guinea, which will be returned on receipt of a bona-fide tender.

Sealed Tenders, endorsed "Electric Lighting, Town Hall," and addressed to the Chairman of the Town Hall and Parks Committee, must be delivered at the Town Clerk's Office, Town Hall, Burnley, on or before WEDNESDAY, the 18th day of January, 1893.

The Committee do not bind themselves to accept the lowest or any Tender, and parties tendering must do so at their own expense.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 762.—Vol. XXX. FRIDAY, DECEMBER 23, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

Until the publication of a properly audited balance-sheet, it is hardly fair to criticise the attempts of the St. Pancras Vestry to compete with private companies in providing an electrical supply. The report which has been issued, although it purports to show "the cost and the financial and general results of the first year's working," must be regarded as a popular epitome of the undertaking. No details of engineering interest can be extracted form the statements of expenditure and revenue, since the number of units supplied is not given. The receipts for current supplied amount to some £7,500 for the first year's working, while coal cost £2,306, wages £2,301, and salaries £689. The general result is a "balance" of £1,068 "towards payment of interest and repayment of loans," allowing nothing for depreciation. We hope to see the St. Pancras Vestry making a profit at 6d. per unit at night and 3d. during the day, but they can hardly expect to do so for some little time to come. Certain calculations for the future are based on an income of £1 per 16-c.p. lamp per annum; and at a meeting of the Vestry, Mr. Eccleston Gibb observed that he had this on the authority of an expert. While some supply stations in London fail to get even 6s. per 8-c.p. lamp per annum at 7d. a unit, this statement is, indeed, worthy of an electrical expert.

At the opening meeting of the year now drawing to its close the President of the Institution of Electrical Engineers commenced his vigorous defence of "Electrotechnics" as follows:—I beg to thank you for the great honour you have done me in electing me your President for this year—a year which the need for a new complete Index of this Society's Journal marks out as closing the second decade of its life . . . It was, therefore, highly satisfactory to learn at the last meeting of the year that this hint had borne fruit, and that so invaluable an index was approaching completion.

Index-making has ever been deemed a fine art by bookmen, but with the deluge of printers' ink continuing to pour down upon us with ever-increasing intensity, intelligent and intelligible index-making bids fair to become an absolute necessity. Unless, indeed, we are prepared to calmly contemplate the spectacle of scientific investigators frequently devoting the best years of their lives to a barren repetition of experiments, buried perhaps, in the guideless maze of some Society's journal, unprovided with even the rudiments of an index to lighten the toil of looking up the results obtained by previous workers in the field.

Dr. Fleming has recently directed attention to two phenomena which sometimes occur at the moment a transformer is connected with, or disconnected from, the mains. One is a sudden rush of current, the other a momentary rise of voltage. These effects may be closely connected, and, indeed, one may cause the other; yet they must be carefully distinguished, since only the second effect, the rise of voltage, is likely to have any harmful influence on the transformer. The sudden rush of current is over so soon that there can be no injurious heating caused in this way; but an impulsive rise of potential, however momentary, may quite possibly break down the insulation of the transformer. In our correspondence columns this week Mr. Lucas calls in question Dr. Fleming's explanation, and suggests that the sudden rush of current is due to condenser action in the coils of the transformer. The suggestion of a capacity effect is an important one; but the coils of an ordinary closed magnetic-circuit transformer have a very minute capacity, considered as a condenser, and we cannot credit that any appreciable change in the current can be caused in this way.

As regards the importance of the phenomenon which our correspondent calls in question, it must be remembered that it is only supposed to occur under a rare combination of circumstances. When the conditions are better understood it will probably be a very easy matter to prevent the phenomenon ever causing a breakdown to occur; but until they are known it seems that a perfectly good transformer may occasionally give way in an unaccountable fashion. Unless we are mistaken it was experience of this kind that led Mr. Mordey to experiment on the subject immediately after Dr. Fleming published his paper.

Alternating currents in ordinary use are generally assumed to be of so high a frequency that they are incommensurable with most of the mechanical motions of every-day experience, and the recital by Mr. Mordey of experiments in which contacts were made and broken by hand actually at different portions of a single period, was received with some surprise. It might have been supposed that the inevitable arc would have bridged over several periods, but experiment showed that this

Hosted by Google

was not the case. It might also have been supposed that the application of ordinary alternate currents to an induction coil through the usual contact breaker would have given rise to confusion with troublesome sparking at the wrong end of the apparatus, and that, on the other hand, a coil containing one hundred turns on the primary and eight thousand on the secondary, acting as a one to eighty step-up transformer simply connected with an alternate current supply would have given some noticeable result. Experiments made by Dr. Lewis Jones, and described in our correspondence columns this week, show, however, that the contact breaker worked as comfortably with alternating currents, as with direct, and the usual length of spark was given at the terminal of the secondary, viz., one and a-half inches, being equivalent to about 35,000 volts. But, as is well known, this high voltage is due to the sudden make and break of the primary, and accordingly, when the contact breaker was screwed up, less than 1,000 volts were produced, and the current being a minute fraction of an ampere, the sparks were hardly measurable.

In the course of an interesting letter which Mr. Tesla sends us this week in connection with the subject of high-frequency alternators, it is stated that the ordinary rules of the magnetic circuit do not hold good for such rapidly changing currents. Our experience with these currents is so limited that it is quite impossible to say whether the striking phenomena to which they give rise can or cannot be accounted for by the old and well-known laws of electricity. Mr. Tesla has suggested that high-frequency currents are quite harmless physiologically, but no one has ever measured them, and the "skin effect," caused by the tendency of currents to crowd towards the surface of conductors, is of so great importance at these high frequencies that the actual currents are probably very much smaller than they are generally supposed to be. For a similar reason, before applying the laws of the magnetic circuit, the effect of eddy currents in the iron must be carefully borne in mind. Profs. J. J. Thomson and Ewing have shown that, even with such slow alternations as 100 $\sim$, eddy currents considerably disturb the distribution of the lines of force in plates of iron of only half a millimetre thickness. With a frequency of more than 100 times that of ordinary alternating currents, these effects will be of very great importance, and it is idle to talk of the laws of the magnetic circuit unless the eddy currents have been taken into consideration. As regards the power of iron to follow the changes of the magnetising force, it has been conclusively proved by the experiments of Prof. J. J. Thomson and others that iron does really remain magnetic for currents which reverse 20,000 times per second.

The problem of distributing and diffusing light from powerful sources, especially from arc lamps, by strictly optical means, is one of great geometrical interest, and has the appearance of practical utility. A note by M. Frédureau in the *Comptes Rendus* describes globes of moulded glass, the surface being covered with prismatic rings. The fascination of this problem lies in the complete and perfect solution which is possible. But on putting it into practice, among the troubles which arise are the exact focusing of the source of light, the warping of the glass during annealing, and the difficulty of moulding large pieces of glass. But when all this has been overcome an insuperable objection is presented by the task of keeping such globes clean. Anything deeper than the pattern of glass used in the street lighting of the City of London will give trouble by the lodging of dust in the grooves. A minor difficulty, but one which has prevented the adoption of such diffusing glass, is the ugliness of the outlines which are demanded, either by theory or by the exigencies of glass moulding, but, as we have seen no illustrations of M. Fredureau's designs, we cannot tell whether he has avoided this.

Although the electrical engineer undoubtedly occupies in the United States "a position of greater freedom and less responsibility" than anywhere else, it would seem that it is not in England alone that the species is beset with difficulties. In France the fancy for supplementing direct municipal taxation by an indirect income from various monopolies has resulted, so far as electric lighting is concerned, in something like a complete *impasse*. Gas is in possession, and, as the Americans say, "has come to stay." An appreciable proportion of the French local authorities have divested themselves of all right to moderate the demands of the gas companies by introducing a little wholesome competition, and the opening of the public roads by anyone but a gas man seems to be a crime of the first magnitude.

The curious result of this curious state of things has been that the down-trodden consumer has risen in his might. A Fédération Nationale des Consommateurs has been formed; a meeting has been held at Lyons, and half-a-score of resolutions have been passed, No. 8 of which runs somewhat as follows:—"Although electricity offers far greater advantages than gas, municipalities shall not grant it any monopoly or privilege whatsoever, but shall facilitate the laying down of central stations *in order to force the gas companies to lower their prices*." A very obliging, but hardly encouraging, proposal. Reactions of all sorts are apt to be violent, and that against monopolies is evidently no exception to the rule. It must, however, in fairness, be stated that the protestants have, in several instances, had the courage of their convictions. In one town gas consumers recently "went back to oil," rather than tamely submit to the charges of the local gas company. In another, our French friends propose to give an even greater proof of their being in earnest; rather than pay a high price for a bad service they swear to abstain from talking—at least, through the telephone.

Colchester.—The Town Council has approved of the draft Electric Lighting Order.

Royal Institution.—Sir Robert Ball will deliver three "juvenile lectures" on Astronomy at the Royal Institution on December 27th, 29th, and 31st, at 3 p.m.

Liverpool Overhead Railway.—The Liverpool overhead railway is to be opened on February 4th next. The Marquis of Salisbury has accepted an invitation of the Directors to perform the inaugural ceremony.

Hosted by Google

Bridgend.—At a meeting of the Local Board last week it was resolved that application should be made for a Provisional Order to enable the Board to construct works for the purpose of lighting the town with electricity.

The Proposed Land Lines Across Africa.—It is understood that Mr. Rhodes will personally urge on the Egyptian Government his proposal to link Egypt (telegraphically) with South Africa by land line through Central Africa.

British Association.—A movement is on foot in Canada to invite the British Association to visit Canada in 1895. The Canadian Institute is now sending a formal invitation to the Association. Toronto is suggested as the place of meeting.

Ogmore.—On Monday evening last Tynewydd and Nantymoel in the Ogmore Valley, near Bridgend, were lighted by electricity for the first time. The low-pressure system is employed. The light has been adopted by nearly all the principal shops.

Junior Engineering Society.—A visit to the Central Telegraph Office and the General Post Office, St. Martin's le Grand, will be paid by the members of this Society to-morrow (Saturday). Meeting at the main entrance of the former building at 2.30 p.m. Groups D, E, and F.

Kingstown.—At the last meeting of the Town Commissioners the Surveyor and the Solicitor handed in a joint report in reference to the proposed adoption of electric power in working the tramways between Dublin and Dalkey. They were of opinion that the adoption of electricity would confer the most signal advantage upon the township and the general public.

The Hampstead Vestry.—At a special meeting of this Vestry held on Thursday evening last week, it was decided by 30 votes to 4 that the Vestry should itself undertake the supply of electricity in the parish, that a Central Lighting Station should be erected in the parish stoneyard, and that application should be made to the London County Council to advance the sum of £25,000.

Bordeaux.—The Directors of the Bordeaux Gas Company have decided to institute proceedings against the Municipality for having, contrary to their agreement with the Gas Company, allowed electric lighting stations to be established. During the year ended June 30th last, 970,000 thousand cubic feet of gas were sold, as against 977,000 thousand cubic feet during the preceding twelve months.

The St. Luke, Chelsea, Electric Lighting Company.—We are informed that this Company will commence to lay the mains on the 1st of January, 1893, and will be ready to supply current by the end of January. We are informed that the Company intend to lay mains along Cheyne-walk, up Oakley-street by King's-road and Church-street to Elm Park Gardens, with an eastern branch supplying Tite-street, Tedworth-square, Smith-street and the eastern end of King's-road.

The Proposed Teaching University for London.—The following memorial, numerously signed, has been presented by Sir Henry Roscoe to Earl Cowper, Chairman of the Royal Commission on the Gresham University:—"The undersigned desire hereby respectfully to record their strong opinion that the foundation of a Teaching University for London, without due provision being made for higher education and original research, would be unworthy of the metropolis, and would entail the neglect of an admirable opportunity for promoting the advancement of science and learning."

The City and South London Railway Extension.—At the last meeting of the Lambeth Vestry the General Purposes Committee reported having considered the memorial in opposition to the shaft with a hoarding round proposed to be erected by the City and South London Railway Company in Clapham-road, opposite the present station of the Company. The Committee directed the officers to give notice to the Company that the proposed site was objected to by the Vestry, and the Committee suggested that if any shaft in a public thoroughfare was absolutely necessary, then that the same would be less objectionable if placed in Studley-road. After some discussion the recommendation of the Committee was adopted.

Obituary.—The death is announced of Mr. Thomas C. Hodgkins, whose munificent gift of £20,000 to the Royal Institution was made a few weeks since. Mr. Hodgkins was born in England. Emigrating while young, he established a confectionery business in New York and made a fortune. Thirty years ago he retired and took to farming on the coast of Long Island. About a year ago Mr. Hodgkins sent a donation of £40,000 to the Smithsonian Institution at Washington, and still more recently he gave £20,000 to the New York and Brooklyn Societies for the Prevention of Cruelty to Children, and another £20,000 to societies for the protection of animals. Among other benefactions was the gift of a public library at Setanket, Long Island. Not long ago he handed a "retainer" of £6,000 to a physician in return for a promise of constant attendance as long as medical services might be required.

Electricity in Railway Signalling.—In his report on the recent railway accident at Kentish Town, where a train travelling to Victoria was run into from the rear by an express train from Bradford to St. Pancras, Major York, who attributes the accident to the negligence of the Kentish Town signalman who allowed the train to enter the next block without notifying the signalman in charge of the section, calls attention to what he considers a weak point in the present mode of block working, viz., that part of it which depends on the obedience of signalmen. Regulations of the most careful and satisfactory nature may be drawn up, but absolute compliance with them cannot at all times be ensured, and he suggests, for the consideration of the Company, whether it would not be possible to adopt on busy sections of the line some system of electrical interlocking which would prevent a signalman from lowering his starting signal without the permission of the man in the cabin next in advance.

Windsor.—There is a good deal more, writes a correspondent, than meets the eye in the dispute between the Town Council of Windsor and the Windsor Electric Lighting Company, which culminated in the police-court proceedings reported in another page. Technically and strictly, the Company have been in the wrong all through; but, on the other hand, the Town Council have played fast and loose with them to a large extent, and the sympathy of the bulk of the inhabitants is with the Company. The truth is that if they had not thus taken the bull by the horns and forced the hand of the Town Council, they would have been indefinitely stultified, and the machinery they had already set up would probably have gone to rust before the Corporation would have removed their prohibition. Declining to undertake electric lighting on their own account, and for the benefit of the community, the Corporation as a body have, from the granting of the Provisional Order, discouraged and obstructed the efforts of the Company.

The Taxation of American Electrical Manufacturing Companies.—As we have several times stated, manufacturers are dealt tenderly with by American tax-gatherers. In this connection an important question of taxation has been decided by the Supreme Court of Pennsylvania, in the case of the Commonwealth against the Westinghouse Electric and Manufacturing Company. This Company, organised under the laws of Pennsylvania, claimed that it came within the provisions of the statutes of that State, exempting from taxation the capital stock of corporations "organised exclusively for manufacturing purposes." The Court of Common Pleas of Dauphin county held that the Company *was* a corporation organised exclusively for manufacturing purposes, and actually carrying on manufacturing within the State, and, therefore, that no portion of

Hosted by Google

its capital was taxable. The Supreme Court of the State, however, have reversed this decision. Looking to the Acts under which the Corporation was organised, it was found to be empowered to engage in enterprises so vaguely defined that it would be unsafe to say what it was *not* authorised to do, except to issue its own obligations as currency.

The Australian Cable Service.—*The Times* of Monday contained the following:—

The representatives of New South Wales, Victoria, South Australia, New Zealand, Tasmania, and Western Australia, have signed, on behalf of their respective Governments, an agreement with the Eastern Extension Telegraph Company increasing the charge upon Australasian telegrams by 9d. per word—*i.e.*, making the rate to Australia 4s. 9d. instead of 4s. per word, which was the amount paid last year under the guarantee arrangement entered into between some of the Colonial Governments and the Company, under which the rate was reduced from 9s. 4d. to 4s. per word, the loss being equally divided between the two contracting parties. Up to the present the Indian Government have made no sign of abandoning their expressed intention of increasing the transit rate upon Australasian messages from 35 to 50 centimes per word. The Secretary of State has conveyed to the Indian Government the strong representations which the Colonial Governments have made against this decision, which they regard as most unreasonable, inopportune, and unfair to the colonies; but since no response has been made, it is thought that the Indian officials will be hard to impress. As it was important that the changes of tariff should be brought into operation on the 1st prox., it became necessary to sign the agreement without waiting for a definite reply from India. The Colonial Governments will continue to press their objections to the increased Indian transit rate, as they have placed on record that if it is insisted upon it will involve the colonies in very serious loss, and may lead to a return to the former high tariffs.

The City Lighting.—At the meeting of the Commissioners of Sewers held on Tuesday, the Streets Committee brought up a report in reference to a letter from the Board of Trade, asking the opinion of the Commission as to an application of the City of London Electric Lighting Company to be allowed to keep all accounts for the public lighting in the three City districts as one account. The Committee recommended that no objection should be offered, providing the accounts for public and private lighting were kept distinct. This was adopted. Mr. C. T. Harris, however, observed that the Company were constantly seeking concessions from the Commission without giving anything in exchange in the public interest. In regard to an application by the same Company for permission to construct 21 converting stations beneath the public ways, the Committee suggested that the application should be complied with under the engineer's direction, but the Court adopted an amendment by Mr. Morton, M.P., restricting the number of stations to twelve, and making them subject to removal at the pleasure of the Commission. At the same meeting Mr. Wood called the attention of the engineer to the effect that the electric light had failed in Cheapside and on Ludgate-hill.

Long-Distance Telephony.—An experiment in long-distance telephony was tried at the residence of the editor of the *Yorkshire Post*, at Leeds, on Sunday evening last. For about two years Christ Church, Birmingham, has been fitted with telephonic transmitters. On a few occasions the effect has been tried in towns at a distance of 50 or 60 miles, and, as a rule, the service has been successfully transmitted. The distance between Birmingham and Leeds is, however, 150 miles, and the transmission had in this case to pass through three exchanges before it reached the listeners. The experiment was, it is said, highly successful. The visitors, says the *Yorkshire Post*, took their seats fifteen minutes before time, and found much preliminary interest in the tolling of Christ Church bell, which rolled into the ear 150 miles off with an almost deafening clang. It was noticeable, too, that the sound of the bell was associated with that subdued rustle and velvety footfall which is a part of the atmosphere of a church during the few minutes preceding the service. At 6.30 the bell suddenly stopped, and then for a few minutes the imps of "induction" were in possession. When they surrendered the wire to its lawful uses the congregation were found to be in the middle of a hymn, which, however, was heard intermittently.

Derry.—The *Gas World* is our authority for the following statements:—Some members of the Londonderry Town Council caused application to be made to the Local Government Board for a loan of £40,000 to carry out an electric lighting scheme, and when that body pointed out that this was in excess of the borrowing powers of the city the sum was reduced to £35,000. Then, when it was stated that it would be necessary to have a public inquiry, the amount asked was again reduced, this time to £15,000. One little fact elicited in the evidence given at a public inquiry last week, may, says our contemporary, to a certain extent, explain the conduct of the councillors. Originally it was intended to supply current for private and public lighting; but the proposal to use electricity for the former purpose was so coldly received that it was abandoned. Perhaps if efforts had been made to ascertain whether the ratepayers desired the streets to be lighted by electricity it would have been found that there was no need to make application for a loan, or to incur the expense of a public inquiry. However this may be, the inquiry has been held, and in many respects it was a farce. The representatives of the Corporation repudiated their own application for £35,000; they also repudiated the map of the scheme, which is said to be officially endorsed; and they disclaimed responsibility for some of the features of that scheme.

The Chicago Exhibition.—The recent public announcement of the proposal of the authorities to close the Exhibition after sunset has naturally caused considerable dissatisfaction, especially in electrical circles. The *Street Railway Gazette* delivers itself as follows on the subject:—"The position which the Directors of the World's Fair have been in the habit of assuming has been a curious one. Since the start, their method of ascertaining the will of the people on any subject relating to the Exhibition has been to take some outlandish position, and then to watch the howl of remonstrance immediately set up in every corner of the country. It would be too great a discredit of the common sense of the management to consider them capable of believing that the real wishes of the people demanded the transformation of this fairyland into a dungeon at sundown. To say that everybody is heartily disgusted with these unrivalled exhibitions of wire-pulling and selfishness is putting it very mildly."—The Royal Commission for the Chicago Exhibition are arranging for a series of introductions to the different sections of the catalogue of the British Section. Amongst those who have promised to contribute articles are:—Sir Douglas Galton, "Railways"; Prof. Francis Elgar, "Ships and Shipping"; Prof. Roberts-Austen, "Metallurgy"; Prof. Le Neve Foster, "Mining"; Mr. W. H. Preece, "Electricity"; Mr. H. Graham Harris, "Engineering"; Capt. Abney, "Photography." The general introduction to the catalogue will be written by Sir Henry Trueman Wood, the Secretary to the Royal Commission.

Taunton.—Sir Thomas Blomefield and Major Cardew conducted an inquiry at Taunton on Friday last, on behalf of the Board of Trade, into an application made by the Town Council for permission to undertake the lighting of the town by means of electricity. Mr. Fleetwood Pritchard appeared as counsel for the Corporation, and Mr. Austin for the Gas Company. Mr. C. P. Clarke represented the memorialists against the grant. Mr. Pritchard said that the existing system of electric lighting was excellent, and contended that there was a general desire to purchase the Electric Light Works. The price of the Works was to be £9,300, and if the Works were not bought by the town they would be closed. Three and a-half miles of streets were now lit by electricity, and the number of incandescent lamps now in use in the town was 915, as against 490 twelve months ago. Evidence supporting these statements was called. Mr. Austin and Mr. Clarke, speaking for the opposition, contended that the purchase of the Works would entail a most serious burden; that, although the light was good, the Company had been carried on at a great loss, and if taken over by the town it would be disastrous to the ratepayers. The Company had become virtually bankrupt. In support of this contention Mr. Gisbert Kapp was called. He estimated that with the necessary extensions, new plant, &c., the Works would cost the town £19,500, including the purchase money. It would cost £3,640 per annum to keep the Works going, and he estimated the income at £2,650. In closing the inquiry Sir Thomas Blomefield said Taunton was one of the best-lit towns he had visited.

THE TEACHING OF SCIENCE IN SCHOOLS.

BY HENRY CUNYNGHAME.

One of the most striking characteristics of our modern system of education is what is known in public schools as the "modern side." The middle and elementary schools may be described as having nothing but a modern side. With the growth of the modern side has sprung up what is termed the teaching of science. The name science is usually reserved for chemistry, physics, physiology, biology and botany, which have been introduced gradually into all our schools with a view, as it is thought, of affording a logical mental training on the one hand, and of being practically useful upon the other. Against these sciences, when properly taught, there is, of course, nothing to be said. Against the present mode of teaching, then, there is very much to be said. The burdened ratepayer, who feels that the zeal of the School Board has almost eaten him up, who sees his rates increase, but without any apparent increase in the capacity of the men who come to mend and to bungle over his drains, his roof, and his waterpipes, may well be pardoned if he sometimes feels tempted to doubt the efficiency of our boasted school system, and to say of science that we could do without it. The puzzled mother, whose daughters come home from the Board schools with their heads full, not of sewing or cookery, but of skeletons and human anatomy, has long ago given up in despair the attempt to understand what objects our modern education has been attempting to achieve, and contents herself with the remark that it is all very wonderful but she does not understand it. The truth is that no one can understand it, and the more he learns and knows the more incomprehensible it all appears.

If there is one maxim in education more certain than another, it is this, that what is learned should be learned thoroughly and intelligently, and that ill-digested knowledge is useless, nay, positively detrimental to the intellect. And yet it is not too much to say that our present methods of teaching physics to the young entirely violate this maxim. If any one wished that his boy should attain a competent knowledge of physics he would of course ground him in the three R's of science, namely, geometry, algebra and trigonometry. Without these very little progress can be made. How much of the pages of *The Electrician* could be understood by one ignorant of them? Nay more, how much could he understand of the simplest mechanical newspaper? And yet, incredible as it may appear, the money, the time, and the energies of the School Board teachers are being at present spent, not in preparing a modest yet firm foundation upon which a future knowledge of science can be raised, but in going through a jargon of science primers, literally building in the air, without any foundation at all. It is, of course, a pretty experiment to show a class the Leyden jar, and the attractions of some pith balls. As they become more advanced the magic word "potential" is introduced and a sort of pretence made at giving them some notions of "energy," but what a farce the system is when considered as a mental training. And how deplorable, nay tragic, the farce becomes when we reflect that the money and time are being wasted which might have been used in equipping the boys with the machinery by which they might easily master these things for themselves. The whole system is precisely like the curriculum of the ladies' finishing schools, in which were taught flower painting in water colours, and the use of the globes. And what is the result? That after a certain number of years of misspent time our young workman, or as he is now termed, young gentleman, comes from his Board school with the airs of a monkey who has seen the world, but without the monkey's mother-wit and intelligence. His mind, exercised in being made to pretend to understand things, but always being taught to evade the difficulties, becomes apish, effeminate, and unfit to cope with the difficulties of life.

A distinguished professor of science, whose name were I to mention it would be familiar to the readers of *The Electrician*, declared to me that with a few exceptions his whole class consisted of a set of self-satisfied prigs—and these exceptions were young men who had been brought up on the classical side. And no wonder. In classics a boy at least acquires habits of careful thought and accurate expression, while the wretched untrained student of our modern text-books, in which whole branches of study have to be compressed so as to sell for 3s. 6d., never even comes in contact with a mental problem.

Let anyone take up one of these text-books. Let us select one of the very best of them, written by a man who in point of knowledge is probably the highest authority in England on the history of his subject—let us take Prof. Silvanus Thompson's "Electricity and Magnetism." Imagine an unfortunate reader, ignorant of mathematics, trying to get through this book. He commences with attractions of pith balls, induction, Holtz machine, and is introduced to that interesting animal, the electric eel. This in 70 pages. He next commences magnetism, and gets on pretty well till he comes to the law of magnetic force which varies as the inverse square of the distance. If he is fortunate enough to know what the word inverse means he, perhaps, surmounts this, but two pages further on he finds himself entangled in the method of oscillations, and informed that he is to take it for granted that the square of the number of vibrations of a pendulum made in a given time is proportional to the accelerating force acting on the pendulum. Having a few pages further on reduced his mind to confusion by the introduction of some trigonometry, the professor's heart softens, and, filled with compunction, he proceeds in a small printed note to explain what a sine and a tangent are. The reader then passes to a description of batteries, which is fairly comprehensible, but soon all hope must desert him, for in a moment, in the brief space of three pages, he finds himself struggling with the theory that the force of the current i acting on a magnetic pole m at a distance r is equal to $2\pi i/r\ m$ dynes. If he looks out "dynes" in the index he finds it is explained at p. 208, and now let him follow the professor, if he can. Unless he has had a preliminary training in dynamics *he cannot*, and no wonder. Can the problems which puzzled Galileo, and which were even left half solved by Newton, be comprehended by a reader with the help of two pages of small print in a note? We pass over the fact that when treating of water-electrolysis chemical symbols are introduced and manipulated (another slight difficulty), and that knowledge is presumed of atomic weights, and chemical equivalents of Dalton's laws. These are merely by the way. The real difficulty is now to commence, for we are at p. 194 introduced to "potential." From that time forth the reader who is not fairly well versed in mathematics had better close the book.

The above remarks are not intended as anything but complimentary of this excellent work, but it is nothing less than a farce, that in a book of such difficulty the writer should be obliged to pause and give his reader some notion of trigonometry. It shows that he knew that it was to be read by those ignorant of mathematics, and who were miserably cramming, or rather being crammed, to go through some grant-earning or prize-getting examination. It is time that there should be some plain speaking upon this subject. The professors and teachers know the truth. It is time that the public knew it also. It is time that smatterings of astronomy without geometry, smatterings of electricity without algebra, and smatterings of light, sound, and heat, without a knowledge even of the laws of harmonics, should cease, and that parents and School Board members should know that in sending boys to learn those subjects without the necessary equipment of mathematical knowledge, they are wasting the time and muddling the brains of those to whose abilities we must trust for the future greatness of England. The amount of mathematics required for elementary physics is not large, and could be acquired without any very great difficulty. As a ratepayer, I have no objection to contribute to teach the sons of other people geometry, mathematics, and trigonometry and mechanics. When they have learned them I have no objection to contribute to teach them the physical sciences, but I have an objection, and believe that others share it, to seeing my hard-earned money wasted in a manner that would disgrace a fashionable ladies' school, and that is calculated to produce a set of scientific *dilettanti*, not an educated class of artisans and engineers.

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Continued from page 190.*)

Fig. 6 shows diagrammatically a complete circuit, including a coil with iron core. A generator is indicated at *a*, and a gap which can be closed at *g*, while for the present the dotted line *c c* may be disregarded. Now a current flowing steadily as represented by the arrow heads, will cause the same polarity of the coil here as in Fig. 1; though this would of course be only when the gap *g* was closed, as otherwise the circuit would not be complete. Let it now be imagined that in the first instance the gap *g* is open. There will then be no current flowing, and so no lines of magnetism within the coil. Suppose, then, the gap to be suddenly closed. We may note the immediate effect. A sudden generation and increase of lines of magnetic induction will take place within the coil, which will exercise a counter tendency to make the current flow round the coil in the *opposite* direction to that shown. It will thus momentarily retard the full establishment of the normal main current. But the full current becoming at length established, let the gap *g* be suddenly opened. The result will be a cessation of the main current, with consequent decrease of magnetism within the core. But a sudden decrease of magnetic lines will cause a current to flow round in the same direction as the main current. Hence at the moment of breaking contact, the main current is reinforced with more or less strength and difference of potential, according to the dimensions of the coil and the rapidity of the break. In consequence, a disruptive spark, due

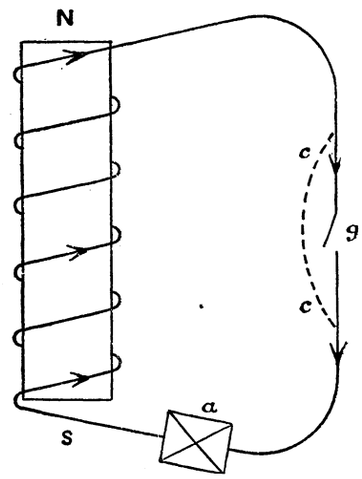

FIG. 6.—Diagram Illustrating Self-Induction.

to the sudden and great increase of potential between the opposing ends, will take place at *g*, leaping across in the same direction as the main current, as in Fig. 3. Yet further, inasmuch as we are dealing here with the main current itself, and not a secondary, if the points at *g* (Fig. 6) are not pulled too far asunder, the current may continue crossing the gap as an *arc*, in the manner already described. It is to be noted that in the cases of Figs. 2 and 3 these self-inductive retardations do actually take place in the primary coils; and while induction sparks are produced in the secondary, self-induction sparks may be produced at the moment of break in the primary.

We thus find in the case of a self-induction spark the effect of Lenz's law again. For the momentary counter current tends to retard the cessation of the main current, although it is the very act of this cessation to which the counter current and the sparks owe their existence. But, as already intimated, these induction and self-induction effects are entirely due to the intervention of magnetism. It is thus that the phrase "electric inertia" is not a safe one to use instead of "self-induction." It is not the *inertia* of the current *per se* that causes it to fly on after a break of contact, and cross the gap in a spark. A high electromotive force may accumulate at the positive electrode at the break; but this is not, correctly speaking, analogous to the high-pressure that may occur behind a valve in a pipe containing water flowing under pressure, when it is suddenly closed. In this latter such pressure is due to the *momentum* of all the water behind the valve, which is suddenly brought to a stop. Momentum implies *weight*. But there appears to be nothing whatever of the nature of weight in the electric current. Hence the cause or causes of effects manifested by an electric current that might seem due to something like momentum must be looked for in an earlier state of things. This is made clear by the fact that if the wire circuit, as in Fig. 6, be pulled out so as to form a simple circuit without any coils in it, and with the iron core also absent, there will be scarcely any self-induction left; and on breaking the circuit at the gap there will be little or no spark, although the actual total length of the wire is unaltered. Thus the absence of any accumulation of electromotive force at the positive electrode in this latter case, shows that there is not anything akin to momentum in the electric current, as with the flowing water suddenly stopped by the valve. With the coils it is a pure case of a sudden *generation* of an extra electromotive force in accordance with the laws of magneto electricity, already dwelt on. This newly-generated electromotive force, impelled by the magnetic forces to which it owes its origin, rises to so high a potential in the positive electrode at the moment of break—it may be to some hundreds or thousands of volts—that it is able at the instant to send a disruptive spark through the air and across the gap in the manner described.

We may turn now to the fifth order of sparks which we have assumed. It has been stated that the sparks of the first three orders are the effects of a high potential difference between the electrodes; though in the second and third orders this will be higher than normal. Our classification is however based on the causes rather than on the effects themselves. Thus, our fifth order of sparks are those that result from a high potential of the normal or main current itself, without any magnetic or other augmentation. It is again an effect of current electricity. Two electrodes, for instance, in a circuit of either continuous or alternating current electricity, of say one ampere and 20,000 volts pressure, if held a few millimetres apart, would have a continuous disruptive discharge passing between them from positive to negative, and that *without previous contact*. This latter characteristic thus alone would distinguish it from an arc. But their brilliancy, as compared with the low luminosity of the arc, that is, of the arc itself, disregarding the intense light from the white hot carbons, and the absence of the intense heat of the latter, together with a difference of the sound produced, would form further distinguishing features. This fifth order, moreover, is not to be confounded with the stream of sparks that may be obtained from a Ruhmkorff or other induction coil. For these latter belong to our second order, having for their cause magnetic generation.

This continuous disruptive discharge of our fifth order, and indeed all disruptive discharges have however a yet further distinct difference from the arc. This is, that they take the most straight and direct course to the negative. An arc, especially of any length, is easily made to take a circuitous path; as for instance in the experiments by Messrs. Siemens Bros. at the Crystal Palace, already alluded to. For here the electrodes instead of being held the one vertically over the other in the usual manner, were held level with each other in the same horizontal plane. Being also about a foot or 18in. apart, the arc then rose from the one 18in. or 2ft. upwards, coming down again to the other electrode, thus forming the shape of a horseshoe or arch. Yet this great divergence from the straight line to the other electrode was chiefly caused by the air draught due to its own heat and the mutual repulsion of its different parts. The arc moreover in this case, was not of a smooth regular form like for example a rainbow, but waved and oscillated, and behaved in a manner that may be better likened to an arched blue flame of fire. The rupturing character on the other hand of the disruptive discharges, is entirely due to their intense proclivity to adopt a straight course. Hence, rather than be turned aside by any obstacle that may be in the way, they prefer to break it up or pierce it, and so attain their desired consummation.

INVESTIGATION OF THE ENERGY CONSUMED BY INCANDESCENT LAMPS.*

BY CH. HAUBTMANN.

The article which I recently published (*see* Abstract in *The Electrician* of September 30th, Vol. XXIX., page 590) on the energy consumed by incandescent lamps has been honoured by a somewhat warm protest from Messrs. Siemens and Halske (*see The Electrician*, December 9th, page 173). Messrs. Siemens and Halske assert generally that the results of my tests are inaccurate, and that their inaccuracy is due either to errors of calculation or defective instruments. The warmth of their letter does not alter my opinion, and I am ready to maintain both the correctness of my figures and the accuracy of my instruments.

First of all, Messrs. Siemens and Halske point out not an error, but an enormity which crept in in connection with the "La Française" lamp of 16 c.p. tested at 110 volts. Well, the figures in columns 3, 4, and 5 of the table relating to this test (see *The Electrician*, September 30th, Vol. XXIX., p. 590) are not the right ones, a fact which I noticed when correcting my proofs. The mistake arose in this way. In transcribing the figures from my note book for the press, pressed for time, I copied candle-power and watts absorbed column by column, and accidentally missed out the first row in the third, fourth, and fifth columns, with the result that I placed opposite the first row of figures of the first two columns figures which ought to have ranged with the second row. In short, the total amperes, candle-power, and watts absorbed per candle related to a test made 250 hours later, the figures relating to the initial test having been omitted. Whether it was that I did not make my correction clear, or whether it was that the compositors forgot to carry it out, the correction was not made, and when the article was published I noticed the mistake, and several others of minor importance, and in the next issue the following erratum was made :—

"*La Francaise*" *Lamps marked 16 c.p. and 102 volts (110 volt Test).*

If, as Messrs. Siemens and Halske assumed, I really had obtained 15·7-candle power for the initial illuminating power of these lamps at 110 volts, I should not have omitted to make note of the fact, since I had already observed that at 102 volts the effective initial power was below the nominal figure.

Messrs. Siemens and Halske next reproach me for leading the public to have a bad opinion of their lamps by the publication of my tests. I would remark that I abstained from any comment as to the value of each type of lamp, and that it is Messrs. Siemens and Halske who have brought me to a subject which I did not anticipate I should have to touch upon. I am confronted with measurements of 16-c.p. 102-volt Siemens and Halske lamps, carried out at the Physico-Technical Institute of the German Empire, which lamps apparently only take 2 watts per candle at 110 volts. It is unnecessary to point out that amongst 100 lamps of the same maker, 10 groups of 10 lamps may give very different results, both from the point of view of energy consumption, and candle power. Now, Messrs. Siemens and Halske naturally forget to tell us that they did not choose the worst lamps manufactured by them for the Physico-Technical Institute tests, yet it would have been fair to have done so, and it is an essential matter from the point of view of efficiency. Not wishing to place myself in the same position, I took any 10 lamps, so that it is not surprising that I did not get the same figures that they give in their letter—that is to say, 2 watts per candle at 110 volts. I do not suspect that their result was obtained by carefully choosing and specially manufacturing the lamps intended to be tested. But are we to conclude that the figures with which I am confronted represent accurately the average article manufactured by this firm? As a matter of fact, the lamps which I tested were bought in the open market in order that I might get a good idea of the manufactured article as sold to the public.

In April last 40 Siemens lamps were obtained in Germany. Of these 10 were tested at 102 volts and 10 at 110 volts. The 102-volt test seems to be in agreement with that at the Physico-Technical Institute, since it is not criticised, and will, therefore, be passed over for the moment, and I will only consider the 110-volt test. The difference between the results obtained at Charlottenburg and by myself are merely due to a difference between the lamps themselves, as may be seen by the following extract from my experiment note book. We thus have an average of 25 candles and a current of 0·62 ampere. The difference between the candle-power of the various lamps are, it will be seen, very large, the maximum difference being 12 candles ($c=32$ candles and $i=20$ candles).*

10 Siemens Lamps marked 16 c.p. and 102 volts (110 volt Test).

Number of lamp.	Candle-power.	Amperes.	Life (hours).	Order of extinction.
a	23·5	0·62	210	3
b	24·0	,,	300	6
c	32·0	,,	860	10
d	30·5	,,	850	7
e	21·0	,,	240	4
f	27·0	,,	800	8
g	21·5	,,	45	1
h	29·0	,,	650	9
i	20·0	,,	175	2
j	22·0	,,	260	5
	25·05	0·62		

In the above table there is, therefore, a lamp giving 32 candles and taking only 2·13 watts per candle. It was probably a batch of lamps like this that Messrs. Siemens and Halske had tested at Charlottenburg. However much it may be to the interest of Messrs. Siemens and Halske to prove the contrary, I think they will do me the honour of admitting and accepting as accurate the above results. In practice, two tests made side by side on the same type of lamp taken from the same batch may, I repeat, widely differ. *A fortiori*, two tests made on lamps of more or less recent manufacture, may give very widely different results. My conclusion, therefore, is that the Physico-Technical Institute experiments no more imply the inaccuracy of my own than mine involve the falsity of those.

It is, moreover, inadmissible that, on the same day and with the same instruments, I should make 20 measurements on 102-volt lamps which Messrs. Siemens and Halske recognise as accurate, and on the other hand, 20 measurements, all too high or too low by 20 per cent., on 110-volt lamps. However, in order that it might not be said that I made a mistake and would not acknowledge it, I, on receipt of Messrs. Siemens and Halske's letter, took five of the ten remaining lamps and tested them, with results as given below, from which it will be seen that the average is 26·8 candles per lamp, with 2·54 watts per candle, a figure which differs but little from that previously given (2·7 watts), but 20 per cent. higher than that arrived at in the Physico-Technical Institute tests. I think it would be waste of time to go on carping at the figures. My second test corroborates the accuracy of the first, and if Messrs. Siemens and Halske desire them, the five or six remaining lamps are at their disposal, so that they may themselves confirm what I state.

Lamps.	Candle-power.	Current.
a	27·0	0·62
b	25·5	,,
c	26·0	,,
d	31·0	,,
e	24·5	,,
	134 candles.	0·62

As to the 10-c.p. 102-volt "Gabriel" lamps, I am in a much less favourable position to discuss the matter, since the tests, as was pointed out in a foot-note, were carried out in the laboratory of the Compagnie Continentale Edison. Nevertheless, I am responsible for anything misleading that the tests may have for people who do not read between the lines.

Lamps which have the highest efficiency are also generally those which last the longest. The bad ones—that is to say, those which absorb the most energy per effective candle—having given out, it may happen that the average of the remaining lamps under test is apparently discrepant from the results previously obtained. For that reason I invariably gave the curve of a single lamp of each series in order to avoid in some degree this defect, which is inevitable when one is working with a few lamps. However, to my

* From *L'Electricien* of December 10, 1892.

* In the 102-volt test the maximum variation is only 3·5 candles.

Hosted by Google

mind this defect is not so serious as may be thought. In fact, in these experiments my aim was to ascertain one thing only, namely, the behaviour of a given type of lamp in an ordinary installation. It is the average values which especially concern private consumers or manufacturers employing incandescent lighting; the manner in which the average values are evolved are, doubtless, very interesting, but if I may be allowed to say so, it is secondary.

In a recently published pamphlet Messrs. Siemens and Halske extol the merits of long-lived lamps having an initial consumption of 3 to 3·5 watts per candle, and at the end of the letter addressed to me they boldly vindicated the quality of their lamps. It is no part of mine to notice or deny their good qualities. Nevertheless, I may remark in passing that the 16-c.p. 102-volt Siemens lamp is not what I should call an ideal one. At 102 volts the candle-power falls rapidly, whilst the watts absorbed per candle increase equally rapidly, and, as to the life of the lamp, not a single one of the ten tested by me lasted 1,000 hours. A similar test made at the Compagnie Continentale Edison on six lamps resulted in only one being alight after 600 hours, and the candle-power of that one had fallen by 60 per cent.

I have no more intention than Messrs. Siemens and Halske of discussing the matter any further, although I also have much to say. Our reasons, however, are different; on their side there is self-interest, on mine only truth. Moreover, they would gain nothing by the prolongation of this debate over details. However, I hold myself at their disposal to maintain my own statements and controvert theirs. I am not concerned with men, but with facts. I do not allow myself to be dazzled by the apparent authority of my opponents, accustomed as they are to believe in German supremacy even in the matter of logic, which has no frontiers; and if I have pressed the point it is because I am giving an indefeasible proof of my my sincerity at the same time that I place my figures beyond suspicion.

[M. Haubtmann also reproduces Figs. 10 and 11 of his article. We have not followed his example, since the correction to Fig. 10 is microscopic, and Fig. 11 was not published in these columns. We take this opportunity of mentioning that Fig. 10, p. 591, *The Electrician*, September 30th, refers, as stated in the text, to the "Zürich" lamp, and not to the lamp made by the Société Hongroise, as was erroneously stated in the foot line.—Ed. *E.*]

THE ACTION OF HIGH TEMPERATURES ON METALLIC OXIDES.

In two communications to the Académie des Sciences, printed in the *Comptes Rendus* for December 12th, M. Henri Moissan briefly describes the results of some high-temperature experiments, and an electric furnace by which the results were obtained.

M. Moissan's furnace was composed of two carefully trimmed blocks of quicklime placed one above the other, the lower one being grooved to receive the two electrodes, and hollowed out in the centre so as to form a crucible. In the first experiments a temperature of about 2,250°C. was attained from an expenditure of 1,650 watts (30 amperes × 55 volts). In the second series of experiments a temperature of about 2,500°C. was reached, some 4,500 watts (100 amperes × 45 volts) being expended in the furnace. Finally, with an expenditure of 45,500 watts (450 amperes × 70 volts), 3,000°C. was reached, at which temperature the very walls of the furnace melted and ran like water. The temperatures were measured by M. Violle.

The oxides to be experimented with were ground into powder. The carbon electrodes were previously submitted to the action of chlorine at high temperature, and were then cooled in a stream of nitrogen. The tips of the carbons were at the end of each experiment always found converted into graphite.

Calcic Oxide.—Pure lime submitted to the action of a 50-volt 25-ampere arc quickly become covered with bright white crystals. In the case of the ordinary commercial lime the crystals, very soluble in water, yielded on analysis the following composition:—Lime 97·3, alumina 1·6, silica 0·45, and traces of iron Complete fusion, followed by confused recrystallisation of the molten mass, was only attained by a 70-volt 350-ampere arc.

Strontian.—Strontic oxide crystallised at first like lime. At about 3,000°C. it melted into a transparent liquid, which became on cooling a confused mass of crystals.

Baryta.—Baric oxide became liquid at 2,000°C., and did not appear to decompose at 2,500°C. On cooling, it became a confused mass of crystals.

Magnesia.—Magnesic oxide was crystallised with far less ease than lime. At about 2,500°C it furnished transparent anhydrous oxide crystals. With 70 volts and 360 amperes it was melted.

Alumina.—Pure aluminic oxide melted at about 2,250°C. If a small quantity of sesquioxide of chromium was added, little red ruby crystals detached themselves from the mass. After exposure for twenty minutes to a 25-volt 75-ampere arc the alumina was not only melted but was volatilised.

Oxides of the Iron Family.—Sesquioxide of chromium exposed to a 55-volt 30-ampere arc melted and gave a black mass bristling with little black crystals corresponding to the formula of anhydrous sesquioxide of chromium. Binoxide of manganese on coming into contact with the arc melted, boiled, and liberated oxygen, furnishing the liquid protoxide which soaked into the lime. Sesquioxide of iron melted speedily, and also evolved oxygen, furnishing Fe_3O_4 (magnetic oxide) in a liquid or partly crystalline state. Protoxide of nickel left a fused mass, covered with little transparent green crystals. Protoxide of cobalt produced rose-coloured crystals.

Titanic Acid.—Submitted to an arc of 50 volts and 25 amperes titanic acid furnished beautiful black prismatic crystals, in appearance and properties like protoxide of titanium. If a current of 100 amperes at 45 volts was applied, this protoxide was melted in three minutes, and partly dissociated and completely volatilised after eight minutes.

Oxide of Copper.—Oxide of copper was completely broken up at 2,500°C.

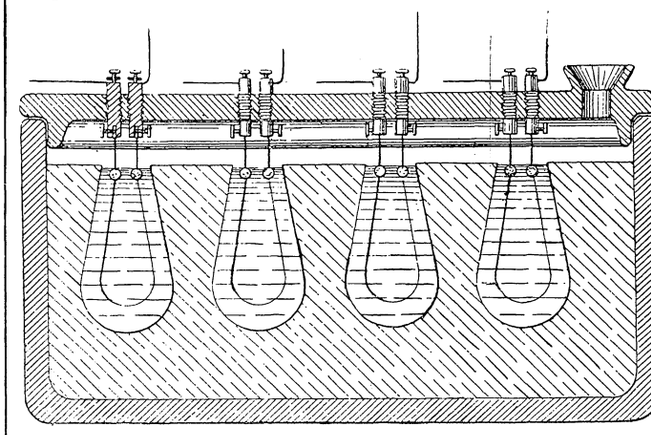
Oxide of Zinc.—Oxide of zinc was volatilised in a few moments. Long transparent flakes were deposited on the carbons, &c.

Oxide of Uranium —Oxide of uranium was reduced at 3,000°C., and in ten minutes a lump of uranium weighing 120 grammes was obtained. Sesquioxide of uranium, heated alone, was converted into long, black protoxide crystals.

In all these experiments a simple elevation of temperature sufficed to cause the metallic oxides to crystallise.

A NEW METHOD OF PREPARING FILAMENTS FOR INCANDESCENT LAMPS.*

The method of making filaments, described in the following article, is used by the Actien Gesellschaft für Elektrische Glühlampen in Budapest.



The filament is constructed in three layers, of which the core is the actual carbon thread. It is soaked with a mineral gum, and is covered with a non-conducting sheath of silicate which melts during the carbonisation and serves not only to protect the filament from burning during the process and from the air, but also to give it a smooth surface on which the third layer (which is necessary to adjust the resistance) can be finely and evenly deposited.

Hitherto the resistance of the filament has been adjusted after fixing in the bulb; but in the present case the thread is completed before being placed in position. It is usual to adjust the resistance by heating in a liquid or gas from which carbon can be deposited; but the currents set up by the heating hinder the process, owing to the contained oxygen acting on the depositing carbon, and spoiling its quality. The filaments are, therefore, heated in this process in a bath of paraffin or naphthalin, or some similar hydrocarbon, solid at ordinary temperatures. Since only the particles in the immediate neighbourhood of the filament become liquid, no appreciable convection currents are set up.

The construction of the bath may be seen from the annexed figure. The complete process is as follows:—The wooden, silk or cotton thread is steeped in a solution of—

Water glass	25 % to 30 %
Senegal gum	10 % to 15 %
Caustic soda	12 % to 13 %

* Abstract from *Zeitschrift für Electrotechnik*, November 1, 1892.

Hosted by Google

It is then rolled, being bent into the form of an angle iron, this form having the advantage of possessing many sharp edges, which, says the *Zeitschrift*, are known to be more luminous than surfaces. The filament is then carbonised in the usual manner, and replaced in the paraffin bath, the paraffin solidifying round it; the necessary arrangements for measuring their resistance are made; the current is passed, and particles of carbon are deposited on the silicate sheath. When the filament attains the proper resistance the current is cut off, the bath of paraffin is melted, and the filament removed; the particles of paraffin are cleared off by alcohol; and the filament is then ready to be fixed in the lamp.

The method is said to possess the following advantages :—The gum gives the filament great toughness and strength. The silicate sheath again strengthens it and forms an evenly-constructed whole. The adjustment of the resistance is much easier, as paraffin is the most suitable hydrocarbon for the purpose of depositing carbon, while the solid bath prevents all access of air during the process.

THE PROPOSED INTERNATIONAL ELECTRICAL CONGRESS AT CHICAGO.

The following is a report made to the Committee of the Electrical Section of the Royal Commission for the Chicago Exhibition by a Sub-Committee, consisting of Profs. Ayrton and S. P. Thompson and Major-General Webber. The memorandum was prepared at the request of Prof. Elisha Gray, Chairman of the Electrical Congress, which it is proposed to hold next year at Chicago :—

The Committee think it well to prelude their recommendations by pointing out that the only International Electrical Congress which has met in the past under Governmental appointment and auspices was the International Congress of Electricians held at Paris in 1881, under the presidency of M. Cochery, Minister of Posts and Telegraphs. This congress was inaugurated by decrees of the French Government, and the French members were appointed officially. It sat during a period of about one month: its expenses were paid under a decree of the Republic dated December 6, 1880; and its objects were described as being intended to "fix" "*la langue electrique universelle.*"

It consisted of one President, three Vice-Presidents, 234 members, 23 officials and secretaries. The delegates represented 28 Governments. Although any delegate could elect to assist at any of the meetings, the representatives were divided generally into three sections, namely :—First: Physists, chemists, physiologists. Second: Telegraphists, telephonists, and railway engineers. Third: Electricians and engineers occupied in industrial and civil and military applications of electricity. The meetings were classified as follows: —First: Full meetings of the Congress. Second: Sectional and sub-sectional meetings. Third: Meetings at which members specially appointed read Papers on specially selected subjects.

At the meetings of the first-named class all subjects of first importance, including reports and recommendations from sections, were discussed, and resolutions of the Congress were recorded. At the second, discussions were held on various subjects, including the careful discussion of questions arising out of the Papers read at the third. At the third, to which the public by invitation were admitted, there was only general discussion, most of the time being allotted to the reading of the Papers.

The subjects to be dealt with at the meetings of the first-named class :—(*a*) Electrical units, and the means of obtaining international uniformity. (*b*) International telegraphy and telephony. (*c*) Discussion of large questions, such as the employment of electricity for lighting, electro-physiology, protection from lightning.

Of the second-named class :—In the First Section : Theoretical questions, electrical measurements, atmospheric electricity, terrestrial magnetism, lightning protectors, questions of electro-physiology. In the Second Section : Telegraphs, telephones, batteries and generators, telegraph lines, lightning protectors, for land lines and submarine cables, induction and interruption, railway telegraph signalling. In the Third Section : Industrial application of electricity, lighting; systems of distribution; transmission of power; time signals, automatic registration; electro-metallurgy and application of electricity to chemical processes.

As regards the meetings of the third-named class, events showed that papers of real scientific value were not easily secured, most writers of the first rank preferring to reserve such productions for the societies which especially deal with the respective branches of science. Besides, it was found that in the very nature of a congress more vitality was imported to the proceedings by the promotion of general discussion than by passing most of the time in listening to papers. For, however able they might be, they are naturally—if of real value—prepared more with a view of publicly recording the writer's views than of being merely suggestive.

The Committee believes, therefore, that the subjects which they enumerate below are of special interest at the present time, and are likely to bring about a useful interchange of information and possible coincidence of opinion; but that it will require careful previous consideration as to the best way of presenting them to the Congress. With this in their mind, the Committee has been led to refer to the work of the Congress at Paris in 1881, and, in connection therewith, to recall an incident which cannot but be gratifying and productive of good feeling at a moment when the great nation then principally concerned is about to undertake a similar task in the interests of electrical science and its applications. It was as follows :—At the meeting of the Congress on Sept. 20 1881, it was proposed by M. Cochery, and unanimously resolved, to suspend the day's proceedings in consequence of the news of the death of President Garfield, in the following terms:—"Je pense qu'en présence du deuil qui frappe une nation amie, l'assemblée voudra témoigner sa sympathie profonde en levant immédiatement la séance."

Subjects on some of which it is proposed that short and suggestive Special Papers might be read by specially selected Members.

Comparison between procedure in different countries.—Methods of avoiding electrical interference, and risks to persons and property.—Units of magnetic quantities, and mode of embodying them in concrete standards.—The adoption of the name "Henry" for the unit of self and mutual induction.—Adoption of the "kilowatt" instead of the "horse-power" as the unit of power.—International nomenclature for describing phenomena of alternate currents, and of electro-magnetic waves.—National and municipal testing laboratories.—Materials for standards of electric resistance.—Points of difference of the electrical vocabulary used in different countries.—The direct conversion of the energy of fuel into electric energy.—Comparison of the various methods employed for the electric transmission of power.—The cost of insulation in relation to high pressure for the electric transmission of power.—Comparison of the economics of the various systems of electric distribution.—Alternate current motors.—The behaviour of transformers when supplying power to alternate current motors.—The construction of condensers for alternate current purposes.—The measurement of power in polyphase currents.—Direct coupled and non-direct coupled dynamos.—The use of equalising dynamos in a three and a five-wire system.—The use of accumulators in central stations.—The proportions between output of dynamos, and the weight of copper and iron employed in their construction.—Electric traction.—Application of electric power in mining.—The adoption of a uniform method of distinguishing positive and negative mains.—Electric supply meters: American, British, Continental.—Criterion of sensibility of galvanometers.—Commercial instruments for measurement of electric quantities.—The relation between the voltage of the arc and the quality and composition of the carbons.—The ageing of glow lamps.—The electric working of metals.—The use of electric and magnetic tests for ascertaining the mechanical properties of metals and alloys.—The best material and mode of erection of lightning conductors in the light of recent researches in electric discharges.—The prospecting for iron by magnetic surveys.—International telegraphy.—Fast-speed and long-distance telegraphy.—The use of batteries or other generators for telegraphy.—Telegraphic lines, land and sea.—Harmonic telegraphy.—Writing telegraphs.—Long-distance telephony.—The possibility of providing telephonic communication without wires.—Application of electric signalling to the working of railways (alarms, time, &c.), and to naval and military purposes.—Magnetic separators.—The use of electricity in engraving and in art reproductions.

The Committee suggest that it would be desirable that a selection should be made as soon as possible, by the American organisers of the Congress, of the actual subjects that it is proposed to deal with, so that, even before it is decided who will be requested to prepare the Papers, and the order in which they will be taken, the delegates of the several nations may be made acquainted with the selected list of subjects. On receipt of that information the British Committee will be prepared, if desired, to suggest names of probable authors, and, if their suggestions be accepted, to arrange with the authors so that the Papers may be ready for the Congress. They suggest that a Committee for the organisation of the Congress shall meet at Chicago immediately before the date decided on for its opening, to arrange, amongst other matters, for the printing of the Papers in full, or in abstract if desirable, and for the preparation of the programmes of daily business.

CONGRESSES AND EXHIBITIONS.

It was inevitable that an Electrical Congress would be held at Chicago from the moment that it was decided to hold a large exhibition in that city, and so long as exhibitions continue to afford amusement to the public and to give opportunity for advertisement to manufacturers and others, so long, also, will such congresses continue to be held. There is reason for supposing that the exhibition mania is on the decline, and most of those energetic gentlemen who adopted exhibition-mongering as a profession have now found other fields for their talents. As a matter of course each show is bound to be bigger than its predecessors, and as an end must come to this sort of thing, since an asymptotic limit is out of the question, it is to be hoped that Chicago will see the last of it, although a World's Fair for London in 1895 is seriously threatened Exhibitions will, of course, continue to be held as attractions at such places as the Crystal Palace, and for special purposes such as the Naval Exhibition and the Frankfort Electrical Exhibition, and further excuses will no doubt be found for illuminated gardens and out-door music; but the progress of such affairs is not usually honoured by the holding of congresses, nor is their termination marked by the distribution of "honours."

Englishmen, it is well known, will celebrate any occasion, even the stranding of an ironclad, by a dinner; and a certain class of scientific men, among whom electricians are the most prominent, cannot pass a summer without a congress of some sort. The British Association, fortunately, satisfies this

Hosted by Google

craving well enough; but every now and then they evince a longing for a feast of chatter, and since the delights of exhibitions naturally attract many visitors, congressers seize upon these opportunities for indulging in the joys of congressing. There is some reason in this; for all such exhibitions have some scientific departments, and many of the best scientific men of the day will brave the mob to see, as best they may, what they want to see; and to catch them and drag them from the turmoil into stuffy lecture halls, and to harangue them in various languages, and to induce them to vote upon sundry resolutions is, perhaps, after all, to do them a kindness, if not to add years to their valuable lives.

The success of the International Electrical Congress at Paris, in 1881, or perhaps it were better to say the importance of some of the subjects which were considered, will ever be held up as an excuse for further meetings. There have been congresses on subsequent occasions, but these have been nearly forgotten; not, we believe, because they were not under "Governmental appointment and auspices," but because there was nothing in particular to be done. A report, which we print in another column, emanates from a sub-committee of the Committee of the Electrical Section of the Royal Commission for the Chicago Exhibition. It has been prepared at the request of the Chairman of the Electrical Congress. No three men called together to prepare a menu for such a feast of reason would have been better able to throw out suggestions. They have evidently done their best to provide, not perhaps a menu, but a bill of fare from which a menu may be circumspectly devised. A good *résumé* of the 1881 congress is given; but it would be a mistake to go over the items, and to point out those which have left their mark as the ones which, after twelve years, should be again discussed; the general class of questions on which action can be taken is probably the same to-day, and will not be found to vary much twelve years hence. The sub-committee are fully alive to the fact that at the 1881 Congress "Papers of real scientific value were not easily secured, most writers of the first rank preferring to reserve such productions for the societies which especially deal with the respective branches of science." This is also true enough when applied to the British Association, and fully accounts for the feebleness of its transactions, and it is no doubt true of any other gathering of a similar kind. Another point of similarity between the gatherings of the British Association and those semi-official gatherings known as International Congresses, is the method of incubation. It is settled in the first place that a congress shall be held, and in the second place a sub-committee suggest topics and propose authors, and afterwards, no doubt, a few more or less honorary secretaries will worry certain unhappy men into sacrificing their time and brains to make a Chicago holiday; for doubtless the congress will lend an air of scientific importance to the show. If, on the other hand, one or two matters of real international importance were ripe for discussion, as in 1881, there would be a valid reason for the meeting. The question then arises, are there any such matters, and what are the subjects awaiting international decision?

On turning to the report of the sub-committee we find an enumeration of subjects which they believe to be of special interest at the present time. But the list contains, unfortunately, little else than suggestions for papers which might with advantage be read at the meetings of ordinary scientific societies, and we might add with distinctly less advantage elsewhere. The list is not unlike the annual circular of the Institution of Civil Engineers; some of the items are too vague—electric traction and electric working of metals; some are too limited—writing telegraphs and magnetic separators. We do not, for a moment, complain of this, for they are only put forward as suggestions from which selections may be made. But amongst them we find one or two matters which may well claim the attention of the congress, since it seems to be settled that a congress is to be held. The adoption of the name "Henry," and of "kilowatt," and the "points of difference of the electrical vocabulary used in different nations," are so distinct from the suggestions which we have just mentioned, that they ought to be placed in a separate class. These and similar questions are, without a doubt, worth settling, but whether it is worth the while of anyone to allow himself to be appointed as a delegate, and to endure a visit to Chicago at the height of its "refulgent summer," is a matter on which we prefer not to express an opinion.

LEGAL INTELLIGENCE.

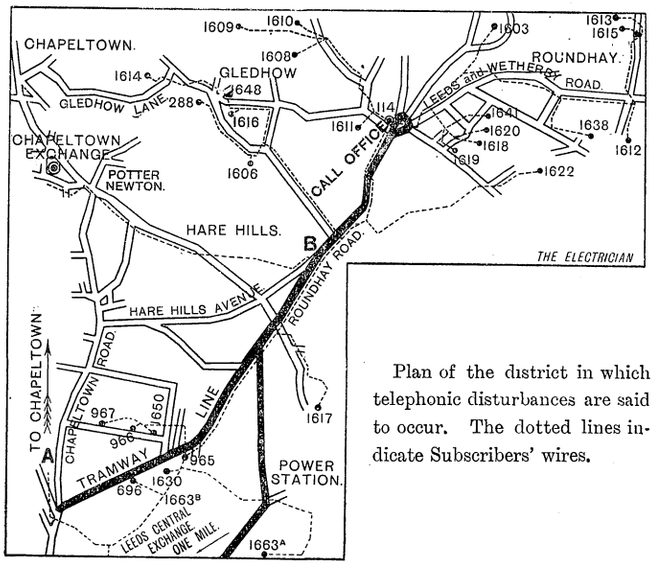
The National Telephone Company (Limited) and another v. Graff Baker.

THURSDAY, DECEMBER 15TH.

On the hearing of this action being resumed on Thursday last week, Sir FREDERICK BRAMWELL was re-called and further examined by Sir RICHARD WEBSTER with regard to the difficulty where there were two double trolley lines running like the head of a T.

Mr. BOUSFIELD: You know already that one of the objections to these double over-head trolleys and conductors is that there is great difficulty in keeping the trolleys on the lines, and they have come off from time to time in the working?—No, I did not know there was more difficulty than there was with a single conductor, except where you have two things you have double the chance you have where you have one thing. It appears to me that you can make those things take the various crossings in the same way as you can make the flanges of the wheel take the crossings of the rail. I should put the difficulty as being on a par with that which exists as to a tramcar getting off the points at a crossing.

Mr. REGINALD ALEXANDER DALZELL was then called and examined by Sir RICHARD WEBSTER. Witness stated that he was Manager of the North Lancashire district of the plaintiff Company. From September, 1891, until October, 1892, he was sub-Manager of the Yorkshire district, which included Leeds. He was thoroughly acquainted personally with the telephonic system of plaintiff Company at Leeds. The



Plan of the district in which telephonic disturbances are said to occur. The dotted lines indicate Subscribers' wires.

Leeds Central Telephone Exchange was at Commercial Buildings, in the centre of the town, with branch exchanges at Chapeltown, Morley, Stanningley and Headingley. There were about 1,200 subscribers, of whom about 1,000 were on the Central Exchange. The subscription was £10 a year. Leeds was practically connected with all the towns to the south, because it could communicate to any of them. The trunk lines were worked in a metallic loop. There were about 18,000 communications per day at Leeds. Up to October, 1891, the system was working very satisfactorily, as far as he knew. The electric tramway ran from two points in the suburbs, shown on the plan, to Roundhay Park. After the first and second days' working complaints began to come in, principally by telephone; people generally telephoned their complaints. Nearly everybody complained who

Hosted by Google

lived or had a connection in the district in which the tramway ran. He did not think they could have retained their subscribers if they could not have improved the condition of affairs. He had personally tried the suggestion made in the Court of taking a subscriber whose earth return would be affected by the tramway back by wire to a distance. He took subscriber 114, who was near Roundhay call office. A line was looped from there to the Leeds Exchange, and one of the wires was put to earth at the Leeds Exchange. There was a slight improvement, but nothing that would do any good. There was certainly not a sufficient improvement to make it commercially useful. The suggestion, indeed, he knew from personal experience with other lines, would not cure the defect. Any part of a circuit passing over a disturbed area, if it communicated with a loop, would cause a disturbance of the whole line.

Mr. BOUSFIELD: When you are working a loop line through a disturbed district it must be insulated?—Yes.

You get to earth and get back the noise?—Yes.

As a matter of fact, it is your practice, is it not, wherever you run through a district where you find your earth return has been disturbed to use what you call a metallic return?—Yes.

Why did you not carry out that practice in the present case?—Because it is not necessary. We do not do it for subscribers' lines. We have no affected areas except where we have these long lines through the country from town to town.

You know that telegraphs do cause disturbances sometimes in your wires?—Certainly.

And if those disturbances are very serious, doubling the wire would cure those disturbances?—Yes, that is so, but I know no case where we have a disturbance on anything except on what we call a trunk line. I have never had to double a subscriber's line.

That will do for my purpose. If the line exceeds a certain length the telegraphic disturbance is serious?—Yes, that is so.

Witness then proceeded to repeat in detail his experiments with No. 114 at Leeds. He had not the slightest objection he said to its being repeated by experts if necessary.

Mr. BOUSFIELD: I suppose you did not test for insulation?—No, I think not; at the time we did not test for insulation.

If the insulation was imperfect, the experiment would be valueless?—I do not know that it would altogether. I am not prepared to say that. I take it, taking the earth back there makes the insulation imperfect; you cannot get a balance on your line with the earth there.

You brought it to earth at the Exchange; but if the insulation between the Exchange and the call office were imperfect, that would have destroyed the value of the experiment as an experiment, would it not?—To a certain extent it would. I think it was a spare subscriber's wire which was used for this return.

Continuing, Witness said he did not make any notes himself. He thought he could identify the wire which was connected. He did not think that in November, 1891, they had any serious snow. There was an interruption owing to snow; but it was not at that time, he thought. One or two trunks were interfered with.

Mr. BOUSFIELD: As a matter of fact, since this disturbance originally took place in Leeds, you have made certain alterations in your system?—None at all. We have made alterations just in the way of business, not in connection with this disturbance at all in any way.

Re-examined by Sir RICHARD WEBSTER, Witness stated that the alteration of 965, 966, and 967 was an ordinary working alteration. For the facility of getting better way-leaves and accommodating some other subscriber, they took the wire straight to the Central Exchange. He was able to state from personal knowledge that the complaints of disturbance from the tram proceeded and went on, and a snowstorm had nothing in the world to do with it.

Sir RICHARD WEBSTER: How was it you got the double metallic return from 114 to the Exchange?—I did it simply for experimental purposes.

Do you remember whether before you put it to earth at the Exchange, before you made your experiment, it was silent, so that you could talk through it in the ordinary way?—When it was a loop without an earth.

Yes?—It was silent.

So that there cannot have been a substantial defect in the insulation at that time?—No; if the one wire went to earth we should get the noise then.

It would not have been silent prior to your taking it to earth at the Exchange?—No; it would not.

Continuing, Witness stated that when subscribers wanted to speak to Liverpool, or distant places, they were charged extra.

Mr. BOUSFIELD: You told my learned friend, with reference to that experiment at 114, that before you grounded your two wires you connected them so as to make a complete metallic loop?—Yes.

And you say that then you heard no noise?—We heard no noises

You suggest that that is a test for insulation?—No; I suggest that both lines must have had about the same insulation. I have worked with lines for more than eight or nine years, and I know if you have a loop line, and there is a disturbance in the neighbourhood, if you put in one single earth on that line, I do not care where you get that earth, you get a disturbance on that line.

You know, probably, that that is due to the electrostatic induction upon the wire?—Yes.

And that experience of yours has been derived upon a long trunk line where you have occasionally, as you have said, got the branch of a tree against one of the wires?—No, I assure you, I was speaking just now about the junction wires—we have a great number of junction wires.

Mr. DANE SINCLAIR, examined by Sir RICHARD WEBSTER, stated that he was engineer and electrician-in-chief to the plaintiff Company. He had been connected with electricity for 21 years, and with telephonic working for 10 years. He superintended the construction of the telephonic system at Glasgow. The whole of the subscribers' wires were on the single-wire system. He had had a very large experience of metallic loops. Making a portion of the circuit metallic and the rest of it earthed would not get rid of disturbances. The metallic loop line, if it could be put over the whole system, would, of course, be the best system. There were, however, from a commereial and practical point of view, countervailing disadvantages in connection with way-leaves, snow, &c., &c.

Cross-examined by Mr. BOUSFIELD, Witness stated that the bulk of his experience with respect to metallic circuits was not confined to the line from Edinburgh to Glasgow. He had experience with almost every double wire in the country, and had tried and tested the system in Paris and throughout the Continent. He went specially round, and among other things he had tested that very thing of earthing such loops, and discussed it with several engineers. They had the double-wire system in Paris. He did not know that the Government had insisted upon the whole of the wires in Stockholm, where there were about 9,000 subscribers, being furnished with metallic returns. He knew that the Government exchange had metallic circuits. The subscribers on one of the exchanges could, he thought, communicate with the subscribers on the other, and the one exchange was worked with metallic returns substantially, and the other exchange was worked with earth returns. He did not try whether that particular part of the system was successful. The system he was very familiar with was working an earth line in conjunction with a complete metallic line, which was done by means of a translator. The cost of these translators varied from 8s. to 20s. He did not think any kind could be made for only a few pence.

Re-examined by Sir RICHARD WEBSTER, Witness stated that there was difficulty in ringing up if they got several of these translators in a line; they also reduced the effective talking. With regard to Paris, they were all underground wires. Overhead wires were not allowed. They had the use of the sewers for laying their underground wires. The Berlin Exchange, one of the largest exchanges in Europe, was all on the single-wire system. It was carried out by the German Government.

Mr. WIILLIAM HENRY MASSEY was next called, and, examined by Sir RICHARD WEBSTER, stated that he had heard the evidence given by Dr. Hopkinson, Lord Kelvin and Sir Frederick Bramwell, and, speaking generally, agreed with so much of it as he could understand. Looked at from an English point of view the overhead wire system was horrible. Of course, in America, it did not matter. English streets were not filled with telegraph poles and telephone poles and electric lighting poles as they were in America; one pole more or less did not matter over there. At Cardiff, they had come to the conclusion, on witness's advice, that an overhead system should not be allowed. If there was a discharge of the same character from an electric lighting as from an electric traction network, he would expect to find the same disturbance. He had been to Leeds himself. He did not go there specially. He heard the telephonic disturbance. In one case he could not get his message through. He prided himself on being able to speak rather well on the telephone.

Mr. JUSTICE KEKEWICH: You are rather good, you say, at speaking?—Yes.

Are you good at hearing?—It depends who is at the other end. I manage pretty well with the American voice, what I call the penny-trumpet voice, and shrill squeaky voice; it is suitable for the telephone. An American voice could go through a fearful noise, which I can discount.

Cross-examined by Mr. BOUSFIELD, witness stated that at Leeds he spoke from the Tramway Company's Central Station to the Steam Plough Works, and also to the Great Northern Hotel in Leeds.

Mr. BOUSFIELD: Do you know whether the gentleman at the other end had the penny-trumpet voice which is so admirable on these occasions? No, he had not; still he has got a pleasant voice—not a gruff voice.

We have not all of us the same idea as to what is a pleasant voice. You are the gentlemen called as a witness from the æsthetic point of view, are you not? No, I am called as a witness to speak to facts.

You do not like the overheard system?—No, I do not. I have seen so much of it that I think it is altogether wrong. I object to overhead things altogether, I think they are a nuisance and unnecessary.

Mr. JUSTICE KEKEWICH: That is rather strong?—It is, my lord.

The heavens are above us?—Everything that can be put underground.

Cross-examination continuing, Witness stated that he was an admirer of the culvert system, but he had not seen it at work anywhere for electric traction purposes.

Sir RICHARD WEBSTER: That is the plaintiff's case, my lord.

Mr. BOUSFIELD: I have communicated with the Solicitor-General, and we do not propose to address your Lordship before calling evidence.

Sir RICHARD WEBSTER: I will now formally put in the license from the Postmaster-General, and the correspondence before action.

Mr. JUSTICE KEKEWICH: What is the point of this.

Sir RICHARD WEBSTER: We gave them notice before they constructed the tramway on this system that they would disturb the telephones and that they did it at their own risk. It is for that reason I wish to read this correspondence. The correspondence, which was between the Leeds Corporation and the Telephone Company, and which commenced on May 14, 1891, was then read. The gist of it was that the Telephone Company, while determined to protect their just rights, and advised by most eminent counsel that they were entitled to restrain the discharge of such powerful currents to earth in such a way as to interfere with their system, were most anxious to avoid any interference with the development of electric traction, whether in Leeds or elsewhere. In a letter dated November 27, 1891, the Telephone Company was referred to Mr. Graff-Baker, and the Highways Committee at the same time reminded the Telephone Company of the privileges they enjoyed in the borough by permission of the Corporation, and the Committee hoped that nothing would arise which would interfere with the good relations at present existing between the Company and the Corporation, or which would render it

Hosted by Google

necessary for the Committee to review the terms upon which the Company used the highways within the district under the control of the Highways Authority. Sir Richard Webster then read a letter dated December 30, 1891, from Mr. Clarance Leighton, the defendant's solicitor :—" Owing to my absence from town yours of the 23rd only reached me this morning. Having regard to the intervention of Christmas and Bank Holiday, and to the fact that it had to be forwarded from Leeds to my client's London office, and thence to me, you will readily understand why you have received no answer before, but lest you should misinterpret my client's silence I wired you this morning as per enclosed copy. My client has received no representation from yours, and has therefore ignored none. It is true that he saw your letter to the Town Clerk, to whom he explained his views, as I am quite prepared to do to you now that you have addressed yourselves to Mr. Baker, but it is somewhat absurd for you to pose as anxious to avoid litigation when all you have done is to write two letters, one threatening action against the Leeds Corporation and the other threatening my client. As you appear to assume that Mr. Baker is wantonly hostile to your Company, I take this opportunity of stating once and for all that such is not the case. He has no desire to interfere with them in the least degree. On the contrary, he frequently makes use of the telephone, and is quite prepared to listen to anything you may have to say. On the other hand, I must point out that my client, as contractor to the Leeds Corporation, is making use of his franchise in a perfectly legal manner, in the manner expressly stipulated for by his contract, and in the only manner that has been found by experience practicable. If, as you state, your Company's telephones are disturbed, it can only be because their instruments are defective. They can be rendered, as you are well aware, perfectly proof against injury by all foreign currents of electricity, whether natural or artificial, at comparatively small expense by the adoption of the McCluer or other systems of metallic return. In the United States and elsewhere the telephone companies have adopted systems which enable them to carry on their business far more perfectly and extensively than your clients do in this country, and this with tramways similar to that of my client running through their midst. I fail to see upon what grounds you claim to ask my client to alter his system. You employ exceptionally delicate instruments ; it is open to you to protect them, and it is your duty to do so. It is a practical impossibility for us to alter our system ; so that if you are right, it means that Leeds must do without an electric railway. In conclusion, I need scarcely remind you that the Thomson-Houston Company has contested the point which you now raise over a score of times in the United States, and in every instance with success. I shall hope to call upon you to-morrow, as stated in my telegram."

Mr. GEORGE WOOD was then called and examined by Mr. DUNHAM, and stated that he was a superintendent of the Corporation Waterworks at Leeds. He was familiar with the position of all the water mains in the Roundhay district. The pipes were cast iron, spigot and socket, joined together by molten lead. In the Roundhay district the diameter of the pipes varied from 6in. to 3in. On July 12th he made an inspection of the water-supply pipes at some of the houses in the Roundhay district. In every case the return wire from the telephone was connected to the service pipes leading to the mains in the streets. The wire was twisted round the pipes about three or four times, and then soldered fast.

Mr. WILLIAM HENRY PREECE, examined by Mr. BOUSFIELD, stated that with regard to telegraph instruments, the earth return had been invariably used for some 50 years past. In practice it had been found that they did not get any serious disturbances, either by tramways or by electric light currents. At Leeds, for instance, they did not find that the telegraphs there were disturbed by the tramway The Post Office had a clause inserted to protect them in Leeds. They had no necessity to enforce it (for telephonic work). The invariable practice in the Post Office was to adopt the metallic return. Fifteen years since he went into the matter, and came to the conclusion that the only possible way of making a telephone work satisfactorily and clearly was to use a metallic return. The Telephone Company had never suggested that the telegraphs were a nuisance, although he knew, as a matter of fact, that they disturbed the telephone wires. The telephone was, without exception, the most sensitive and the most beautifully delicate instrument in the world ; there was nothing to compare with it. There was no more delicate instrument for picking up and indicating stray vibratory currents than the telephone. Cross talk was common. It did not make serious interruption or annoyance in telephonic communication. One got used to it, especially in London. All disturbances were avoided as long as the metallic circuit was complete. Her Majesty's Post Office had between 30 and 40 exchanges. The total telephones worked on the exchange system was 5,382 all over the country. He saw no difficulty whatever in working a telephone system which consisted partly of earth returns and partly of metallic returns. There being disturbances down at Leeds, he had the whole of Leeds carefully surveyed and examined, and he went himself to see how far the tramway interfered with the Post Office wires. He did not think it would be a serious matter to double the Roundhay subscribers' wires.

Mr. JUSTICE KEKEWICH : I should like to know that I understand it. I gather from this map and from what I have heard that the particular district with which we are dealing is what may be called a suburb of Leeds—that is to say, far away from the place that was mentioned just now, the Great Northern Hotel, in the centre of Leeds, and it is not densely populated ; at any rate, there is not a great number of houses. Supposing those conditions were changed, as they might very well be, and you had a great many houses there, side by side in rows and squares. and so on, each of which required the telephone, and you had to supply double metallic returns for every house, then it would come to a very serious matter indeed, and if it is right there it is right in a great many other places too.

Mr. BOUSFIELD (to the Witness): You think it is the right thing to do everywhere ?—I do, undoubtedly.

Witness, in continuation, said that he was prepared to say, generally from his experience of disturbances, that in towns they were chiefly due to electro-magnetic induction. On comparatively short lines electrostatic induction would be absolutely unappreciable. With regard to the suggested doubling back of the subscribers' wires and bringing them to earth near the exchange, it would tend very much to diminish the disturbance. It would remove entirely the disturbance due to electro-magnetic induction over the part duplicated, but it would not interfere in any way with any earth disturbance—that would remain the same. Lord Kelvin had suggested that there would be electrostatic induction still left even on a short circuit. He (witness) did not think from his experiments it was possible to get electrostatic effects on wires of less than 20 or 30 miles. Examined with regard to the distance at which a disturbance might be felt, Witness stated that he had recently been making some very interesting experiments down in South Wales to endeavour to communicate between the shore and the lighthouse, three miles off, on Fleet Holms, and it was very essential to find out where earth conduction came in, and where ether induction came in. In these experiments it was shown unmistakeably that the earth was affected to a distance of two miles around the circuit on which he was experimenting, and it was only when they got beyond two miles that they got into effects of induction. An alternating current of eight amperes at 20 or 30 volts was used. The effects observed between the wires under the Gray's Inn-road and the telephone showing them that they could read a message through a distance of 80ft. had led him on to the inquiry. He doubted whether the doubling of the tramway wires would do away with disturbance of the telephone in Leeds, because one of the essences of a metallic circuit was the power to twist the circuit so as always to maintain the average distance between the inducing wire and the induced wire the same. They could not do that with a double wire for tramway traction. He did not think a complete cure could be secured in any other way than by a complete metallic telephone circuit. It was a complete cure, and a recognised complete cure, and a most effective cure, and he did not see why they should go in any other direction. Apart from the tramways, his view about the telephone as an instrument for practical purposes in the absence of that complete metallic circuit was that it was an ineffective and incomplete apparatus. The use of an earth return for telephones was not really in the long run the most economical from a monetary point of view—quite the reverse. He thought himself that if they improved their service by duplicating the telephone wires they increased their business, and the increased business paid for the increased cost of duplicating the wires.

Sir RICHARD WEBSTER : I am aware that you are a master of expression, but you are the apostle and high priest of duplicate wires for telephones ?—I am.

You have enunciated it for the last twelve or fifteen years ?—I have.

And have used very strong language about it ?—Frequently.

Still, a very large number of people, unfortunately, will not adopt your religion ?—Unfortunately they will not.

The following table was then directed to be put upon the notes :—

LIST OF POST-OFFICE TELEPHONE EXCHANGES.

	No. of subscribers.		No. of subscribers.
Newcastle-on-Tyne	612	Workington	11
Sunderland	40	Liverpool	13
West Hartlepool	29	Cardiff	84
Middlesborough	33	Newport	49
Stockton	19	Swansea	6
North Shields	17	Talywain	10
South Shields	10	Pontypool	6
Tyne Dock	12	Barry Dock	8
Jarrow	3	Tonypandy	6
Blyth	2	Britton Ferry	3
Blaydon	1	Aberdare	2
Durham	1	Merthyr	1
Hull	163	Ebbwvale	1
Leicester	105	Falmouth	4
Nottingham	8	Cork	12
Hinckley	7	Limerick	4
Loughborough	4	Waterford	7
Manchester	12	London Paris	20

Telephones in use at Reuter's offices	4,691
" " Government offices	691
Total	5,382 on March 31, 1892.

The above total includes private lines and exchange circuits.

After having gone over the table, Witness stated that he understood that the National Telephone Company had something like 40,000 or 50,000 subscribers. He knew that the Telephone Company were now paying £45,000 a year to the Government as royalties. He had not considered the question of the best way of constructing a tramway so as to avoid disturbing neighbours.

Sir RICHARD WEBSTER: Did you not establish at Plymouth an exchange on the double wire system and compete for commercial business ?—We established it at the wish of the Plymouth people, and we maintained it as long as they wanted us to maintain it.

Were the Telephone Company misguided enough to come down and compete with you ?—They compete everywhere ; they are a commercial company, we are not.

And the misguided Plymouthians actually preferred the National Telephone Company to you ?—The misguided people did.

And they succeeded in obtaining on the single wire system—this wretched system—a very large number of subscribers, so large a number that in the proper management of your department you shut up your

Hosted by Google

exchange?—Very nearly so; but you must remember that we are not a competing business company—we are simply the Government.

There you were trying to compete?—No.

If you could have made it pay you would have kept it open?—Well, we might.

In continuation of his cross-examination, Witness admitted that notwithstanding his powerful preaching all the telephonic business of the country other than the Post Office had been carried on on the single wire system up to the present. They had had interference by electric currents from the South London Railway and Deptford. These seriously disturbed his telephone circuits; he did not remember whether they affected his telegraph circuits. The disturbance from the Holyhead electric lighting disturbed the telegraph messages on the North Western. In Leeds itself they had had the presence in the telegraph circuits of small currents. He had no doubt that they came from the tramways. He transacted very large portions of his business, and not unfrequently communicated with a number of subscribers on the National Telephone system in London. He had talked successfully on many occasions, but with difficulty. He did not think that to put the telephone system underground was a matter of enormous difficulty. The Post Office found that it was cheaper to put wires underground when they reached a certain number. He did not think that an overhead wire was any better when it was carrying a tramway current than when it was carrying a telephone current. It was equally objectionable in either case. With reference to the question of the difference of expense of overhead and underground wires, the Local Authorities at Wandsworth had tried to get the Post Office to put their wires underground, and the Post Office resisted it and produced figures showing that it cost ten times more to put them underground than overground, but that was one wire. In the case of one wire the difference of expenditure was quite 10 to 1, but where they came to 30 or 40 wires the tables were turned.

Re-examined by Mr. BOUSFIELD, Witness stated that at Plymouth they did not go into the usual arts of commercial competition. The shutting up of the exchange at Plymouth was in no way due to any failure in the efficiency of the system.

Mr. BOUSFIELD: Can you give me a reason any more than you have done why in Plymouth the population all seem to prefer the National Exchange system to yours?—One cannot predicate the mind of the commercial public. It is probably a question of rental more than efficiency.

Mr. JUSTICE KEKEWICH: Do you think it is inconvenient to have underground wires as part of the system, and overhead for another part?—There is no inconvenience at all.

Mr. JAMES SWINBURNE, examined by Mr. BOUSFIELD, stated that he had been called in to examine the defendant's tramway at Leeds, and had gone into the effect which it had upon the use of the telephone in Leeds. He had made careful experiments on the subject in conjunction with Dr. Abdank. The tramway at Leeds struck him as being a very good specimen, and well constructed in every way. He could not find any faults in it. He should not think that the contacts between the trolley and the wire and the wheels and the rail—that was to say, the variation of those contacts—had any substantial effect in disturbing the telephones in Leeds. He was of opinion that the collecting of the current when running was a difficult thing anyhow, and if from two overhead conductors, it was a very much more difficult thing; in addition to that, the double overhead system produced no end of complications. Having regard to the existence of the double overhead conductor system, and the necessities of corners, witness did not think that it was a practicable system to apply in a place like Leeds. Witness was next examined on the various suggestions made by plaintiff Company's witnesses as to how a double overhead conductor system might be worked; he did not think them practicable. As to the Vevey system, that presented more difficulties than the double-conductor system. The Buda Pesth inch and a-quarter slot would never be allowed in a town like Leeds. With regard to his tests at Leeds, he tried the experiment of using a complete metallic telephone circuit, of which two sides were along the tramway, and the third side was straight across country, and the disturbance was practically the same. Then he tried using the double metallic circuit round the two sides, the circuit being tested occasionally, and it was quite clear that if they used a proper metallic system, then, though the tramway wire was close to the telephone at the very worst part of the whole system, the telephone line was quite perfect as regards disturbance. From the result of these experiments he came to the conclusion that there might be some mischief caused by conduction, but it was practically swamped by the mischief caused by induction. He had made an examination of the different instruments which were said to be affected by the trams. He heard disturbances to some extent on a fair number of the telephones. He did not find any of them that he had any difficulty in speaking through, and he did not find that the people at the other end had any difficulty in speaking to him. The cars were in full swing. They went to the telephone office. They gave every facility, and they allowed him practically to call up any subscriber. He called them up one after the other as if he belonged to the Telephone Exchange, and asked them if they had any complaint, and they said no generally. Some had little complaints about the instruments. Then he nearly always put the question: "Are you disturbed by the tramway?" And their answers varied. Sometimes they said "Yes, there is a disturbance," but the general answer was, it was not so bad as it used to be. He asked them all whether they were ever stopped from speaking entirely, and he understood not. The apparent diminution of the disturbance in Leeds was probably due, not to a diminution of the disturbance, but to the people getting more accustomed to it. These experiments were made on May 9, 1892. He thought, if anything, that London disturbances were worse than those at Leeds.

It was then decided to send an independent expert down to Leeds to examine as to the alleged disturbances, and the Court adjourned until January 12, 1893.

Windsor Town Council v. Windsor and Eton Electric Lighting Company.

At the Windsor Town Hall on Monday last the Borough magistrates were engaged in hearing a summons issued on behalf of the Town Council of Windsor against the Windsor and Eton Electric Lighting Company for unlawful proceedings, thus described:—"On the 5th, 6th, 7th, 8th, and 9th of December, 1892, at the parishes of New Windsor and Clewer, within the Urban Sanitary District of the said Borough of New Windsor, (they) did unlawfully displace, take up, and injure the pavement stones and materials of certain streets and highways within the said district, called respectively Peascod-street, High-street, and Thames-street, without the consent of the Mayor, Aldermen, and Burgesses of the said Borough, acting by the Council, being the Urban Sanitary Authority of the District."

Mr. G. H. LONG, town clerk, in supporting the summons, stated that the Company had obtained in 1890 a Provisional Order, the 7th section of which provided that "the undertakers within a period of six months after the commencement of this Order, and before exercising any of the powers by this Order conferred on them in relation to the execution of works, shall show to the satisfaction of the Board of Trade that they are in a position fully and efficiently to discharge the duties and obligations imposed upon them by this Order throughout the area of supply." Until, therefore, the Company had satisfied the Board of Trade that they were in this position, the Order gave them no authority to do anything whatever in the town, and as the Board of Trade had not yet sanctioned their proceeding with the work, they had broken the law. This they admitted, and it remained to be seen whether they could show any reasonable excuse for going on with the work without such authority. The present proceedings were taken under the 149th section of the Public Health Act, 1875, which provided that all streets repairable by the inhabitants at large within any urban districts, and the pavements in such districts, should vest in and be under the control of the urban authority; and that any person who wilfully took up the pavements without authority should be liable to a penalty of £5, and a further fine of 5s. for every square foot of pavement displaced. Assuming that the Company had power under an Order to break up streets, notice must first be given to the highway authority of their intention to do so, and plans must be furnished showing the line of the mains and the distributing wires, and their depth and position. But in this instance nothing of that kind had been done. The object of these provisions was to safeguard the public against accidents, but in this case some accidents had occurred. In consequence of the Company's action in breaking up the streets under such circumstances, the Town Council had resolved that the town clerk should be instructed to proceed against them under the Act mentioned; but they also resolved that he should be instructed to ask only for a moderate penalty.

Mr. T. V. DAVISON, the borough surveyor, in examination by Mr. LONG, said he had measured the pavement disturbed by the Company on the dates given, and found the total superficial area to be 4,711sq. ft. He had received no notice from anyone before the stones were removed; all he had received was a plan, which was sent to him two months ago, simply showing the three streets and the direction of the wires, but not giving the depths or position. No plan had been received of the present work.

Mr. LONG observed that the Company had applied to the Town Council for permission to lay their mains, and the Council, on learning from the Board of Trade that the Company had not complied with the Provisional Order, passed a resoution deciding not to consent to the Company going on with the work.

Mr. DAVISON further stated that notice had been given to the Town Council, the Postmaster-General, and the Gas and Water Companies, as required by the Order, but no notice with plans, as required three days before by the Public Health Act.

Mr. SEVENOAKES, on behalf of the defendant Company, declared that Mr. Davison had received proper notice with plans, and while admitting that the Company had disturbed the streets without the sanction of the local authority, and that technically they had not satisfied the Board of Trade that they were in the actual possession of sufficient capital to carry out the work over the whole area, he observed that he knew of no other company in the whole country that had been able to comply with that requirement But the Board of Trade had power reserved to withhold the revocation of an Order if they were satisfied that the Company were doing their best to carry it out. In this instance the work that had been done had been done with the full knowledge of the local authority, who had been consulted by himself individually, and by the Directors, and who had received several assurances that the company would do everything in their power to carry out the Order. The Board of Trade had shown extreme willingness to assist the Company. The Company had received the verbal sanction of the Board of Trade, and these various circumstances to some extent justified the action of the Company. He further claimed that, so far from the town being injured by what had been done, it would benefit, inasmuch as the pavement, when replaced by the contractors, would be in a better condition than when it was disturbed; and, further, that a large number of men had received employment who would otherwise have been idle. Under all these circumstances he asked the Bench to take a lenient view of the matter, and to be satisfied with inflicting a nominal penalty.

A number of letters between the various parties were put in and read, and in the end the Bench delivered a written decision, viz.:—"The magistrates are necessarily obliged to convict the defendants, as they have admitted having committed an offence The only question is the amount of penalty to be imposed. It is evident that the object of compelling persons to give notice to the highway authority, and requiring that the breaking up of the street shall be done under the superintendence and control of the surveyor, is to provide that means shall be taken to protect the public

Hosted by Google

against accident. This was not done in this case. The amount of the penalty to which the defendants are liable, in addition to the fixed penalty of £5, is 5s. per square foot, amounting to £1,175. We are unanimous in imposing a fine of £2 as a fixed penalty, and in addition, a further penalty of £9. 16s., being at the rate of ½d. per square foot. We regret that the Town Council did not itself take action to prevent the breaking up of the streets instead of throwing the onus of a very unpleasant duty upon the magistrates."

The fine was at once paid, together with the costs.

Muirhead v. Caledonian Telephone Company (Limited).

In the Court of Session at Edinburgh, on Thursday last week, Lord Stormouth Darling had on his roll for trial an action brought by Mr. Andrew Erskine Muirhead against the Caledonian Telephone Company (Limited) for reduction of an agreement said to have been entered into between the pursuer and the defenders in December, 1891, and January, 1892. The pursuer in his condescendence said he was a telephone engineer, and that by the introduction of French telephones at the expiry of certain English patents in 1890 and 1891, he had developed a considerable business, for the carrying on of which the Caledonian Company was ultimately formed, with a capital of £50,000 in £1 shares, 10,000 shares of which had been taken up and 10s. paid per share. The pursuer was appointed Managing Director, and had a salary of £300 and 10 per cent. commission on net profits. In respect of his valuation of his stock, &c., he claimed £2,084. On account of this amount the defenders had paid him £400, and gave him 1,600 shares (10s. paid), valued at £800. The defenders admitted the accuracy of items £1,033 and £150, and the payment to account of the shares, but believed no further money was due, though they were willing to have the accounts adjusted on the action coming before the Court. The counsel asked for a short adjournment, as there was some hope of an arrangement being come to, In the result it was stated that the case had been settled, and his lordship was asked to discharge further proof, assoilzie the defenders, and find neither party entitled to expenses. Part of the arrangement, which was otherwise financial to a small extent, was that the whole of the charges made against the Directors were unreservedly withdrawn.

CORRESPONDENCE.

THE COST OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Although it was not my intention on entering the discussion on the above subject, to claim the suggestion of the sliding scale price for electricity, based on the *maximum demanded*, yet it may be historically interesting to note that I as manager of the Brighton Electric Light Company (then a branch of the Hammond Electric Light Company) drew up and used a contract form in the spring of 1885, from which I extract the following sentence relating to the charge:—"The undersigned hereby agree with the Brighton Electric Light Company to pay them at the rate of one halfpenny per hour per lamp (but in the event of the average daily consumption during the quarter being less than three hours per day, the charge shall be one penny per light per hour), as determined by the meter supplied by the Company." This was modified later in the same year, to the effect that the charge per unit consumed would be one shilling, if over ten were used, per lamp installed, and 1s. 4d. if less than ten were used.

Although there is an obvious flaw in the above scale, and it now seems very badly expressed, yet it will be evident that the suggestion of a price dependent on the number of hours the demand was used, belongs to the ever-electrically-active town of Brighton, and to the good old days when electricity was sold at 1s. 4d. per unit.

As the Brighton Corporation propose from January 1, 1893, to charge for the electricity consumed on the sliding scale basis of 7d. per unit for the first two hours per day the demand has been used (as shown by the yearly consumption), and half-price, or 3½d. afterwards, it is evident that I, as their adviser, after some considerable experience, have not arrived at the same conclusion as Mr. Holmes, of Liverpool, about the difficulty of getting people to understand the sliding scale; or believe that it has any material limiting effect on the number of lamps installed; for under the new tariff I fully expect a considerable increase in that number, owing to the obvious advantage to business houses in being able to get the electric light in their sitting-rooms, when the shop lamps are turned out, at the ridiculously low price of 3½d.

The method of determining the demand will be to install near the meter in every house a thermal type of maximum recording ammeter (as suggested by Prof. Kennedy), which will be read and set back to zero by the Meter Inspector once every month in the two winter quarters; the mean of these six maxima will be taken as the "demand" from which the number of hours per day the lamps have been used, is calculated.

In conclusion, I may add that the result of the present year's supply of electricity from the Corporation's works has been to show that out of a total expenditure of 7d. per unit sold, 5d. was the cost of having the plant in readiness to supply, and only 2d. the cost of producing the unit; thus bearing out Dr. Hopkinson's contention that a uniform charge per unit, without reference to the maximum demand, is financially unsound.—Yours, &c., ARTHUR WRIGHT.

26, Park-crescent, Brighton,
December 21, 1892.

EARTHING THE MIDDLE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There are some points in Mr. Mavor's letter (see *The Electrician*, December 9th, p. 170) which I would ask your permission to comment upon. In his second paragraph, if I understand it rightly, he speaks of experience with earthing as if it had produced bad results in practice. I can but assume that he refers to installations accidentally earthed; the experience with wilfully earthed installations with two wires in this country being very limited. The only ones that I have acquaintance with on land with double wiring are those which I carried out several years ago, and which are now working in the same condition—the *Scotsman* Office in Edinburgh, with about 350 lights, being one, and Storey Bros. and Co.'s installation, Lancaster, being another large one; this latter has several detached buildings with one system of mains, and resembles strongly a town supply. In neither of these installations has anything occurred which could show that the earthing principle has introduced any detrimental effects; on the contrary, many advantages were derived. Judging from the following extract from an article by Von Ph. Seubel, which you published in your issue of 11th November last, it would appear that earthing the middle wire was the absolute cure of the troubles which Mr. Mavor describes as having taken place in America:—"It was only after careful discussions between a number of the officers of the Edison General and the Edison Illumination Companies of New York, that the third wires were put to earth at all the distributing centres, and in the central stations themselves. For three years I was occupied in the construction and maintenance of the underground network of the New York Edison Stations, and can state that before we put the middle wire to earth, we had very frequent troubles, which, in most cases, were due to electrolysis; in fact, not a week passed without a number of disturbances in the network, some very serious and some trifling. From the time, however, we put the middle conductor to earth the network remained perfect and absolutely free from faults for more than three months, and it seemed as if the previously existing strong tendency to electrolytic action had disappeared. Such disturbances as did take place at very long intervals of time were much smaller in extent than had formerly been the case, and it was abundanently evident to us that in addition to other advantages which were obtained by this earthing of the middle wire, it was an indisputable fact that it practically freed the network from all faults, whilst no corresponding disadvantages were observed. No complaints from the Telephone Company ever came to hand to my knowledge, notwithstanding that I was in daily active communication with the officers of the Company."

With regard to Mr. Mavor's comments on the benefit of insurance rules, I see only how they have confirmed old ideas, and how much they have retarded progress. This, in particular, I have been made to feel keenly in my early attempts at earthing and latterly in the introduction of concentric wiring. British engineers and electricians are not the people to establish bad work, proof of which we have in every other

Hosted by Google

industry, all of which have been left to the skill and experience of the parties interested in the subject and unhampered by rules from insurance companies.—Yours, &c.,

J. D. F. Andrews.

41 and 42, Parliament-street, London, S.W.,
December 15, 1892.

P.S.—I delayed this letter waiting the sanction of the proprietors of the *Scotsman* and of Messrs. Storey Bros. to publish the above given information.

THE EWING HIGH-FREQUENCY ALTERNATOR AND PARSONS STEAM TURBINE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of November 18th I find a description of Prof. Ewing's high-frequency alternator, which has pleased me chiefly because it conveyed to me the knowledge that he, and with him, no doubt, other scientific men, is to investigate the properties of high-frequency currents. With apparatus such as you describe, shortly a number of experimenters, more competent than myself, will be enabled to go over the ground as yet but imperfectly explored, which will undoubtedly result in the observation of novel facts and elimination of eventual errors.

I hope it will not be interpreted as my wishing to detract anything from Prof. Ewing's merit if I state the fact that for a considerable time past I have likewise thought of combining the identical steam turbine with a high-frequency alternator. *Anch' io sono pittore.* I had a number of designs with such turbines, and would have certainly carried them out had the turbines been here easily and cheaply obtainable, and had my attention not been drawn in a different direction. As to the combination, to which you give a rather complicated name, I consider it an excellent one. The advantages of using a high-speed turbine are especially great in connection with such alternators. When a belt is used to drive, one must resort to extraordinarily large diameters in order to obtain the necessary speed, and this increases the difficulties and cost of construction in an entirely unreasonable proportion. In the machine used in my recent experiments the weight of the active parts is less than 50lb., but there is an additional weight of over 100lb. in the supporting frame, which a very careful constructor would have probably made much heavier. When running at its maximum speed, and with a proper capacity in the armature circuit, 2½ H.P. can be performed. The large diameter (30in.), of course, has the advantage of affording better facility for radiation; but, on the other hand, it is impossible to work with a very small clearance.

I have observed with interest that Prof. Ewing has used a magnet with alternating poles. In my first trials I expected to obtain the best results with a machine of the Mordey type—that is, with one having pole projections of the same polarity. My idea was to energise the field up to the point of the maximum permeability of the iron and vary the induction around that point. But I found that with a very great number of pole projections such a machine would not give good results, although, with few projections, and with an armature without iron, as used by Mordey, the results obtained were excellent. Many experiences of similar nature made in the course of my study demonstrate that the ordinary rules for the magnetic circuit do not hold good with high-frequency currents. In ponderable matter magnetic permeability, and also specific inductive capacity, must undergo considerable change when the frequency is varied within wide limits. This would render very difficult the exact determination of the energy dissipated in iron cores by very rapid cycles of magnetisation, and of that in conductors and condensers by very quick reversals of current. Much valuable work remains to be done in these fields, in which it is so easy to observe novel phenomena, but so difficult to make quantitative determinations. The results of Prof. Ewing's systematical research will be awaited with great interest.

It is gratifying to note from his tests that the turbines are being rapidly improved. Though I am aware that the majority of engineers do not favour their adoption, I do not hesitate to say that I believe in their success. I think their principal uses, in no distant future, will be in connection with alternate-current motors, by means of which it is easy to obtain a constant, and in any desired ratio, reduced speed. There are objections to their employment for driving direct-current generators, as the commutators must be a source of some loss and trouble, on account of the very great speed; but with an alternator there is no objectionable feature whatever. No matter how much one may be opposed to the introduction of the turbine, he must have watched with surprise the development of this curious branch of industry, in which Mr. Parsons has been a pioneer, and everyone must wish him the success which his skill has deserved.—Yours, &c.,

Nikola Tesla.

AN INDUCTION COIL ON ALTERNATE-CURRENT SUPPLY MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As an illustration of the point raised by Dr. Fleming in his "Experiments on the Magnetic Behaviour of Transformers at the Moment of Connecting them to a Circuit," the following experiment may be of interest:—

An induction coil, capable of giving 1½in. sparks, was supplied with an alternating current at twelve volts from a transformer on a house-lighting circuit in the Metropolitan Electric Supply Company's district. The coil has one hundred turns in the primary and eight thousand in the secondary, and, therefore, acted as a one to eighty step-up transformer. The length of spark from its secondary coil was too short to measure, and but little alteration could be noticed in its behaviour towards a vacuum tube when its condenser was arranged in shunt to the primary. But when the same alternating current was supplied to the coil through the contact-breaker, and that was allowed to vibrate, then the full length of spark (one and a-half inches) again appeared abundantly.—Yours, &c.,

H. L. Jones.

LUMINOUS DISCHARGES IN EXHAUSTED TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The suggestion in your Editorial Note of December 9th, as regards the objection to the use of the term "current" in referring to the luminous discharge observed in bulbs and tubes surrounded by a coil of wire, through which a Leyden jar is discharged, calls for a few remarks. Doubtless, the term "electric current" is not a happy one under any circumstances, but, as it is universally employed, it is necessary to put up with it. I fail to see, however, that it is more inapplicable to the discharge in the tubes than to cases in which it is usually employed, *e.g.*, the current in an electrolytic cell. As regards the necessity of a closed circuit, we know that when dealing with alternating currents it is not a requisite condition, as there is an undoubted current in the conductors joining an alternating dynamo to a condenser, or in the rods of a Hertz oscillator.

In the case of a spiral coil round a straight tube there is no trace of a return circuit, unless the faint luminous glow filling the whole tube act as such, which I think extremely improbable. I do not imagine, however, that a return is necessary. The magnetic induction is strongest near the wire, and its rate of change is large enough to produce an electric stress sufficient to break down the rarefied gas close to the wire, resulting in a molecular convection current parallel to the wire, which tends to charge one end of the tube positively and the other negatively. Immediately this stress is removed these charges reunite (this may partly account for the faint glow which pervades the whole tube, and which I have never seen entirely absent, though, when the spiral discharge is very bright, it is hardly noticeable). The discharge from the jars being oscillatory, there will be a swinging backwards and forwards of the molecules close to the wire, thus giving the luminous spiral, as, in this swinging, the molecules will probably be caused to "wriggle" by the violence of their collisions, and thus give out light-waves. To obtain a bright spiral it is necessary that the wire should be very close to the tube, and it is consequently

Hosted by Google

advisable to use bare wire. The best results I have obtained hitherto have been with an exhausted tube 13cms. in length and 2cms. in diameter wound with a spiral of 4 turns, 2½cms. pitch, of bare copper wire No. 23 B.W.G. With this, by properly adjusting the spark gap, a very bright and clear spiral can be obtained. Lengthening the pitch of the spiral rapidly reduces the brilliancy of the discharge, though I have, with one of about double the above pitch, obtained very fair results. With a straight wire I have, up to the present, been unable to get any trace of a straight luminous band, although a faint luminosity is sometimes visible in the whole of the tube.—Yours, &c., E. C. RIMINGTON.

The Park, Norwood, S.E.

GILBERTIANA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Silvanus P. Thompson has seen fit to publish a letter in your columns as remarkable for its inaccuracy as for its bad taste, and I shall be obliged to you if you will afford me space to correct the former, the latter being his own affair.

Prof. Thompson appears injured because a hard-working and singularly erudite American is publishing a translation of "De Magnete," the only conceivable reason for this emotion being that such a publication will make more ridiculous than they are at present, the hitherto sterile pretensions of the Gilbert Club, about which such a fuss was made some years ago by Mr. Thompson. Since when did this abusive Professor possess an international copyright in "De Magnete"?

The following facts may be of interest. Last autumn Mr. Mottelay came to consult me as to the course he should adopt with regard to the richly annotated translation he had made of Gilbert's book. He was divided between two opinions. He hesitated to do what he thought might interfere with the vague intentions of the Gilbert Club, and he was very reluctant to allow injustice to be done to the "De Magnete," a result he feared would inevitably follow, owing to what he considered Prof. Thompson's surprising want of knowledge on the subject.

I strongly advised him to publish, urging his absolute right to do so; the folly of allowing the great labour he had devoted to the subject to be wasted; the apparently doubtful, and, in any case, the limited issue of the Gilbert Club programme; and, taking his statement for granted, the imperfect character of the translation, if it ever were published. Mr. Mottelay decided to follow my advice, and Prof. Thompson may, therefore, look to me as being primarily responsible in the matter.

The reputation of Messrs. J. Wiley and Sons needs no defence at my hands against the scurrilous attack of Prof. Thompson. They rank as high as any publishers and gentlemen in the world. It is true that they published American editions of Ruskin's works; but it is also true that they exhausted every possible means to pay a royalty on these works, and only abandoned the attempt when, after several years, Mr. Ruskin refused to negotiate. Prof. Thompson may learn more of the standing of Messrs. Wiley and Sons if he ventures to attend the Electrical Congress at Chicago next year.—Yours, &c., JAMES DREDGE.

London, December 20, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am indeed very sorry that my friend, Prof. S. P. Thompson, deemed it advisable to give publicity to the letter which appeared in your issue of 9th inst.

Prof. Thompson is often referred to in my class of experimental physics as an authority on methods of winding electromagnets, on measuring the number of magnetic lines that thread through a given circuit, and, I may add, on dynamo-electric machinery in general; but I am sorry to say that his letter has led me to conclude that he sometimes allows his pen to run in advance of his knowledge. In a man with any pretensions to science, this is hardly pardonable.

If Prof. Thompson had known the negotiations that took place between Messrs. Wiley and Sons and Ruskin's publishers, if he had known the offers made by the great New York firm years before any copyright law was concluded, he would never, I feel sure, have committed himself to so *gratuitously* injurious a statement as that put forward in his letter about Mr. Mottelay's translation of Gilbert's "De Magnete," and his prospective American publishers.

May I say, Sir, that several of my pupils and electrical friends—interested in the great work of Dr. Gilbert—have frequently asked me, during the past three years, what is or what may be the probable period of incubation of Gilbert's great work. Doubtless Prof. Thompson has carefully diagnosed the case, and will, with his usual courtesy, enable me to give a satisfactory answer to my class when we meet after the Christmas holidays.—Yours, &c.,

Tooting College, Dec. 20th. M. F. O'REILLY, D.Sc.Lond.

[If we are rightly informed, Mr. Ruskin's works were reprinted in anything but a high-class fashion, in direct opposition to his wishes; and if we understand Mr. Ruskin's views on such matters, the offer of money in condonation of this act would add additional insult to the injury.—Ed. *E.*]

PROF. AYRTON'S MAGNESIUM CELL AND HIS EXPERIMENTS ON THE MIGRATION OF GOLD THROUGH MERCURY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On my return from the Continent to-day, I read Prof. Ayrton's reply to my letter published in *The Electrician* of December 9th, and if you will allow me, I shall now add a few further remarks. Prof. Ayrton agrees with me that the high E.M.F. of the magnesium-mercury cell can neither be explained by the chemical combination of the two metals nor by a thermo-electric effect of the usual kind, but is probably due to the interposition of some foreign substance between the magnesium and mercury. Whether this foreign substance be moisture or acid, as suggested by me, or magnesium oxide as supposed by Prof. Ayrton, is not very material, so long as it is conceded that it partakes of the nature of a compound body and an electrolyte, since there is nothing remarkable that a cell, consisting of two metals and an electrolyte, should show such a high E.M.F. electrometrically.

The formation of a thin film of oxide, or more probably hydroxide on the surface of the magnesium wire appears to me very plausible, inasmuch as I observed the very same thing many years ago with aluminium wire (*Nature*, Vol. XXVI., p. 245). When a freshly-scraped aluminium wire was brought into contact with mercury, and the resistance measured from time to time, it was observed that a gradual increase took place, which sometimes almost rose to infinity. The same was observed without mercury, when two aluminium wires were twisted together, but then oxidation proceeded much more slowly. If mercury is boiled with aluminium in vacuo, and then exposed to the air, it soon becomes covered with a growth of greyish-white alumina, which in reflected light shows a blue colour, evidently due to finely divided metal uniformly distributed in the substance.

With reference to the supposed electrical transference of gold through mercury, I mentioned only one cause in my former communication which would tend to convey gold to the bottom of the tube, viz., the circulation in consequence of inequalities of temperature; but it is quite obvious that when gold is placed on the top of mercury it will also descend, on account of its higher specific gravity. If, however, the gold is introduced at the lower end, and mechanical disturbances and changes of temperature are avoided, it will probably take an extremely long time before it reaches the uppermost strata. To substantiate this I need only recall the well-known experiment on the very slow upward diffusion of copper sulphate in water.

I remember having seen tall glass cylinders containing concentrated copper sulphate solution at the bottom, and colourless water above, which had been standing in a suitable

Hosted by Google

locality for over a year. During the quickening of the mercury surface by the electric current mentioned by Prof. Ayrton, such violent disturbances take place that it is not at all surprising the gold should be rapidly distributed throughout the mercury.—Yours, &c., EUG. OBACH.

Woolwich, December 17, 1892.

P.S.—I just see in the last number of *Nature* that Prof. Erdmann, of Berlin, has also noticed the formation of hydrate of alumina on amalgamated aluminium. My own observations were made 20 years ago, and the hydrate then formed I still have in my possession; even now it shows the bluish colour quite distinctly.

THE RUSH OF CURRENT ON CLOSING THE PRIMARY OF A TRANSFORMER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have followed with much interest the series of experiments with transformers which Dr. Fleming describes in the current number of *The Electrician*. There is one point, however, in regard to which I have not been able to arrive at any degree of clearness. Why does Dr. Fleming assume that the rush of current, which he *alleges* takes place occasionally on "making" the primary circuit of the transformer, is due to a persistent magnetic condition of the core? Surely, nothing would have been easier than to test the magnetism of the core on each occasion that the current was switched on; but I do not gather that Dr. Fleming did this. Is it not equally, or more, probable that the alleged phenomenon was due to a condenser effect? This could easily be ascertained by earthing both coils of the transformer when out of connection with the mains, and if it turn out to be the case a simple appliance for earthing the coils of the transformer when disconnected would prevent the rush.

I have ventured to use the word "alleged" in this connection, as, though a certain slight difference of spark is no doubt occasionally observed, practical experience seems to show that the "rush" is never sufficiently formidable to give rise to any danger of collapse, and that transformers are daily connected with and disconnected from the mains without the occurrence of any mishap.—Yours, &c.,

8, Featherstone-buildings. R. N. LUCAS.
Dec. 20, 1892.

ELECTRICITY SUPPLY AT IPSWICH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We thank you for the second of your notes in your last issue. May we ask you, however, to be good enough to correct therein the statement that "Messrs. Laurence and Scott carry on an electrical supply business at Ipswich."

We disposed of this business over six months ago, expecting that the Ipswich Electricity Supply Company (Limited), would carry it on and develop it, but we regret that the Company has not so far fulfilled these expectations, and, owing to the announcement of the sale of its plant, we wish it to be clearly understood that the Company is in no way under our management.—Yours, &c., LAURENCE, SCOTT AND CO. (LIMITED),
W. B. Sisling, Secretary.

Gothic Works, Norwich, Dec. 20, 1892.

WOODHOUSE AND RAWSON UNITED (LIMITED).

The annual general meeting of the shareholders of this Company was held yesterday at the City Terminus Hotel, when there was a large assemblage of the shareholders. Sir Rawson W. Rawson occupied the chair.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN stated that the desire of the Directors was that the shareholders should be given the fullest information on all matters concerning the Company and should be placed in a position correctly to estimate the position and prospects of the Company, and form a judgment as to the wisest course now to be pursued. At considerable length he analysed the losses which had taken place during the past year, in order to show the causes from which they had arisen, and to demonstrate to them that these causes were exceptional and would not recur. The first of these, as shown in the profit and loss account, was that on lamp settlement and action £14,472. Their Company was prevented by the result of the action of the Edison and Swan Company from manufacturing or selling incandescent lamps in the United Kingdom, and as the result of this injunction they were prevented from utilising their valuable lamp patent, which had made the reputation of the Woodhouse and Rawson incandescent lamp. Subsequent to that action the Company, under the best legal advice, entered into an arrangement with the British Electric Light Company to work under the licence which that Company had obtained from the Edison-Swan Company. Owing, however, to a technical legal point, they found themselves subsequently in a position in which there was no alternative but to give up all attempt to contiuue the lamp manufacture, or to run the risk of incurring heavy damages at the suit of the Edison-Swan Company. By these means they were deprived of one of the principal expected sources of industrial profit, and in order to settle the action of the Edison-Swan Company they had to incur the large loss mentioned, the major portion of which was due to the necessary writing down of the stock and plant in that department. They retained their lamp plant and expected in next November, whenever the patents of the Edison and Swan Company expired, to resume the manufacture, with the advantage of the reputation which they had already established for their incandescent lamps. The next item was loss at Kidsgrove, amounting to £17,000 odd. The loss had been on contracts taken over from the vendors, and on work taken by them while the vendors were in the service of the Company. The losses were also due to debts which were incurred by the failure of the vendors' firm. In the matter of the Kidsgrove purchase, the Directors considered themselves justified in relying to a great extent on the judgment of their then business manager. Under the present management all the contracts undertaken, with a very few exceptions, had been profitable. A large amount of business had been taken up and successfully carried out, and a still larger amount, reaching a total of nearly £50,000, had been offered them during the last few months, which they could have undertaken if they had had the necessary capital. The third item on which he would remark was loss on trading and depreciation, amounting to £37,000. As far as they could make out, nearly £30,000 of this might be stated to be depreciation, and not actual trading losses. A portion of the loss was due partly to agencies which had since been closed as unprofitable, and the initial expense in the formation of new branches, several of which had only been in operation for the last four or five months, and were now beginning to pay their way. Among the most promising he would specially refer to Johannesburg, Sydney, and Paris. A great deal of the loss on trading was due to the working of their Cadby Hall Factory, which since their lamp business had to be temporarily closed, could not possibly be carried on with a profit. These works they proposed almost entirely to close after Christmas for a while, transferring their manufactures to Manchester and Kidsgrove works. By these means standing charges which had amounted to as much as £6,000 a year, would be converted into an annual profit of £500 or £600, which would be increased to a very considerable amount as soon as they were able to resume their lamp manufacture. The depreciation of stock, plant, and tools represented 25 per cent. off the cost price to the Company, which the Directors had thought wise to have written off. The sum of £5,650, which constituted the next item for depreciation on patents, was the proportion they had decided to write off each year from the amount at which their patents stood in their books. As they took no credit for new patents, they were satisfied that due provision was made for securing that the value of their patents was not unduly estimated. During the last year they added over 20 patents of more or less value to their list, most of which had been acquired at a mere nominal cost. It was only in cases where the invention, if realised, would be worth a large sum to the Company, such as £20,000 or £30,000, that they thought of spending anything but a few pounds or, at the outside, a few hundred pounds on developing it. One exception to this rule he might mention—namely, the Epstein patents. In that case it had been sufficiently shown to their experts, after a trial of more than two years, that this accumulator patent of Mr. Epstein was destined to prove one of the most valuable electrical inventions of the day. As to the criticism why the Woodhouse and Rawson Company undertook the business of promoting other electrical companies, the answer was clear. Among the patents which were brought to them were some involving necessarily so vast an outlay that it would be impossible, if it were expedient, for their Company to undertake the manufacture itself. At the same time, some of these patents were of very great value. Having now gone through the several losses shown in the balance-sheet, he might point out that they had depended not so much upon loss in trade as upon depreciation of stock, which they could not help, and the depreciation of securities, which they could not help, and which was not certain. He then referred to a special report of the auditors, as alluded to in their certificate to the accounts, and said that the necessity for this report arose from the fact that they were obliged to present their report and balance-sheet to the shareholders before the end of the year, and that, owing to the confusion caused in their accountant's department by a change of staff that was necessary, the required information and vouchers could not earlier be laid before the auditors. As the best compromise that could be effected, therefore, the Board determined to request the auditors to give such certificate as they were able to do with the materials laid before them, and to qualify their certificate in a report, which should be laid before the shareholders. Several of these questions, which were open at the date of the auditors' signature, on the 12th instant, had since been cleared up. He then read the report of the auditors, and gave further explanations required to clear up those which remain. With reference to the vouchers which still remained to be produced, the Board had no doubt that they would shortly be forthcoming. The amount was not large. The question of repayment of the guarantee fund was one upon which it was due to the shareholders that he should enter with some detail. The paragraph in the original prospectus was founded upon a clause in the agreement of this Company with the vendor Company, Woodhouse and Rawson (Limited). Having read the clause he said two interpreta-

Hosted by Google

tions were possible of it. The first which was urged upon them by the vendor Company, was that if at any time during the three years they made sufficient profits to pay a dividend of 15 per cent. for three years the fund would at once be free from any obligation, and could not afterwards be drawn upon to make up the deficiency. The other view, which was taken by the Directors of this Company, and which he would assume for the present purpose to be the correct one, was that they were at liberty to make up from the guarantee fund the amount due to complete the 15 per cent. dividend if the profits available fell short of that amount. At that time last year, when the question came up for discussion, the prospects of the Company were extremely promising. In the first place they had secured the valuable concession of electric lighting of the Champs Elysées, in Paris, half the capital for the working of which concession had already been obtained by them in France, and, but for the extreme depression which prevailed in the Money Market in this country, there should have been (and the Directors foresaw) no difficulty whatever in providing the other moiety of the necessary capital. The profit to this Company should have been not less than £40,000 if that concession had been worked by them, but, unfortunately, they were unable to find the necessary share capital in this country, and one opportunity for making a profit was lost. Secondly, they had in their hands at that time the valuable Oncken and Epstein patents, both of which they anticipated being able to realise in the course of the present year. The Oncken patents they did realise, though at a very much reduced price, and owing to the comparatively small amount of capital subscribed in that Company they were obliged to take their profit, reduced as it was, in shares. That profit, as was stated in the report, did not show in last year's balance-sheet, as the Oncken Company was only brought out after the close of the financial year. The Epstein Company they had preferred to postpone bringing out. In addition to these three sources of what should have been very handsome profits, there stood to the credit of the Company a reserve of £43,000, represented by the investments now standing to their credit. It seemed, therefore, sufficiently clear that there was no reasonable probability of the profits of the Company from one or more of the four above-mentioned sources proving insufficient to pay the 15 per cent. dividend, and what the Directors could not but view with considerable anxiety was the obligation under which they lay of having in great probability to find £75,000 in cash to repay the vendor Company on the 1st of July in the current year. Of course, had the £75,000 remained intact in the bank from the first commencement of the Company, no difficulty could have arisen ; but inasmuch as the Company had, under the powers conferred upon it by the agreement with the vendor Company as mentioned, availed themselves of the right mentioned in the prospectus to employ this capital in the business, the fund was no longer in existence, and they were confronted by the alarming obligation to provide it by July 1st. Under such circumstances, they came, after a most careful and anxious consideration, to the conclusion, which he felt sure they would agree was the correct one, that if they could persuade the vendor Company to accept a considerable portion of the sum to be repaid in Debenture stock of this Company instead of in cash, that would be taking the best course in the interest of this Company. This, after much negotiation, they succeeded in arranging, and compromised the claim of the vendor Company in the month of January last by a payment of £12,000 in cash, and £51,000 in Debenture stock, and a special meeting of the shareholders authorised the Directors to carry out this arrangement. With regard to finance, the present position of the Company was this: it had cut down its expenses by a very large amount, and with the reductions which it contemplated carrying out before the end of this month, it would have got rid of all the sources of loss. In the industrial portion of the business the incomings would then at once be more than equal to the outgoings, and, they had every hope, would bring in during the year a very fair profit ; but for this purpose it was necessary to buy off the debts that they had incurred during the past, and to provide an adequate working capital for the loss. To enable the Company to buy in cheap markets, and to maintain its credit, the Directors estimated that the sum required was £60,000, and they proposed to raise this amount by mortgaging their free investments, amounting to over £70,000, and the stock-in-trade and merchandise, which amounted, at the date of the balance-sheet, to nearly £100,000. This would not interfere with the existing debentures and Debenture stock, as the proceeds would be chiefly used to pay off existing liabilities, nearly the whole of which was at present secured upon securities of different kinds, and more especially to pay off the amount that they had borrowed upon their uncalled capital, and thus save the necessity of making a call at the prsent time. The rate of interest to be paid was a high one, namely, 10 per cent. per annum, but it was only a temporary loan for a short period (one year), and as it would be issued *pro rata* to the shareholders and debenture-holders of the Company, they would have the benefit of this high rate. The balance would enable them to undertake profitable contracts which were offered to them at home, and which, as the business manager, Mr. Stutchbury, would presently inform them, were ready to their hands to the extent of £30,000 to £40,000, as soon as they had capital to undertake them. The loan would be charged as a specific charge upon the stock and merchandise in hand, two trustees being appointed. By this method the Company would obtain time to realise the investments and patents that it had in hand to recoup itself for the loss of the previous year. He concluded by moving the adoption of the report.

Lieut.-General Sir JOHN STOKES seconded the motion.

Mr. SQUIRE said he did not think the Directors were at all likely to be able to raise more capital until a good deal more was known about the actual position of the Company, and he would move, but not at all in a spirit of hostility, an amendment that the report should not be adopted, and that a committee of investigation should be appointed. In the first year of its existence the Company made a magnificent profit—at least on paper. It paid a dividend of 15 per cent on the ordinary shares, £30,000 was carried to reserve fund, and £16,000 carried forward. The shareholders were induced by the apparent great prosperity of the Company to part with the sum originally lodged with the Company as guarantee for the dividend of 15 per cent. for three years. In the second year of the Company's existence things were not nearly so rosy, and there was just sufficient to pay the dividend of 15 per cent. on the ordinary shares. The picture on the present occasion was very greatly changed, and instead of earning handsome profits, or even ordinary profits, they now showed a loss of £129,000. It was very difficult to offer any explanations to account for such a sudden change ; but he had noticed before that new industrial companies had a particular knack of being exceedingly prosperous at the commencement, and of then collapsing. This was particularly the case when the whole of the shares at the beginning had not been planted on the public. For the first year or two the profits might be made to look almost anything they liked ; but, of course, this could not be continued. The guaranteed fund of £75,000 was one of the main inducements to investors to put their money into the concern, and that being so he thought that the fund should have been sacred for the purpose for which it was originally intended. He himself voted against the proposal that was made for parting with it, but he preached to deaf ears, and the matter was carried through. They now knew what the position of the Company was. He would like to know who the people were who lodged the £75,000 in question.

Mr. SAMUEL POPE, Q.C. (one of the Directors), stated that £60,000 of the amount was in the business now.

Mr. SQUIRE replied that originally the amount was not secured, whereas it was secured now, more or less. With regard to the balance-sheet, bad as it showed the position of the Company to be, he believed it was really a good deal worse. He was himself a chemical engineer, and had been connected with a good many companies. Glancing down the assets, he saw a good many that were of an extremely doubtful character. For example, what was the value of the goodwill of a business which was losing at the rate of £2,500 per week? Then, £73,000 was put down for patents; and as a patentee himself, and an adviser on patents, he knew them to be doubtful property. In fact, a patent was good to-day and bad to-morrow, as some new invention might wipe it out of existence. He, therefore, thought that all patents ought to be written down with the utmost possible speed. He saw that one of their valuable patents had landed them in a lawsuit which had cost them about £14,000. Sundry investments figured for £102,000 altogether, but he shrewdly suspected that if they were to endeavour to realise that item it would not fetch half the sum shown. They were unquoted securities, and probably to a large extent unsaleable. (A voice: Like our shares.) He could not understand himself how it was that the Stock Exchange had persistently refused to quote the shares of Woodhouse and Rawson United, and stockbrokers to whom he had spoken on the subject said there must be some reason for it. He thought that in any case the £73,000 put down as the value of the patents was considerably in excess of their practical value. The Kidsgrove investment had been most unfortunate. Apart from their agencies, their manufacturing works were scattered all over the country, whereas he considered that they ought to be concentrated as soon as possible under one roof. He was certainly not so sanguine as to their prospects as the Directors were, and if they were going to rely on working off the interests which they held in other undertakings, he thought they would be disappointed. He was convinced that the public would not look at any industrial undertaking.

Mr. SAMUEL BACON suggested that the amendment should be altered, and that a committee of shareholders should be appointed, the meeting standing adjourned for three months, so as to afford the opportunity for making up the accounts for the six months which had since elapsed.

Mr. SQUIRE said he would accept this modification, and he would propose the amendment in the terms suggested.

Mr. BACON said that he would second the proposal. He desired that the affairs of the Company should be thoroughly investigated. The balance-sheet had been sprung upon him by surprise. Since its issue a committee of some of the largest shareholders had been going into the accounts, but he did not think they could have obtained all the information that was necessary. When the trading results of the past six months were known they would be able to see whether the affairs of the Company had improved, and what the real position of matters was. The Company had had £600,000 of the public's money, and he could not tell how this sum could have been possibly wasted in the last two or three years. If the proposal of the Directors was carried, this would be something like the position of things: they would have secured creditors to the extent of £22,000, a mortgage on their freehold of £23,500, and debenture stock and bonds to the extent of £164,000, while they would have shares to the extent of £427,000. Now they had a proposal for raising £60,000 on movable stock, but he believed if these powers were given to the Directors, as suggested, the shareholders would never get a penny out of the concern.

Mr. W. GRIFFITH supported the amendment, and said it appeared to him that the Directors themselves had lost faith in the undertaking. He considered that their securities were of the most worthless description, and while their profits were *nil* their expenses were enormous.

Mr. LOCKWOOD also strongly supported the amendment. He said he thought it very possible that the Company had never really earned the dividends that it had paid, and he thought that they would have to call upon the auditors to satisfy them that they had been earned. The Company had brought out a great many companies, but how many could be pointed to as paying interest at the present day. What were they worth in the market now? Many persons had been reduced to poverty by the Company.

Mr. POPE said he was thoroughly ashamed of the balance-sheet. So far as he was concerned, he was in the hands of the shareholders ; but, while he would be glad to hide his head, he would not run away from a

Hosted by Google

concern because it happened to be in a disastrous condition. If they would undertake to raise the Debenture stock mentioned, he would put £2,000 into it on any security. The Directors could not object in the least to what had been said by the shareholders, and he could not imagine any of them feeling the least objection to the appointment of the proposed committee. The Company, however, wanted money to meet its present liabilities, and if the money was not found from some source or another, the creditors would wind it up. The shareholders must therefore understand that although it might be extremely advisable to have a committee to enquire into matters before any scheme was adopted, yet some money must be found, or the whole concern would pass out of their hands into the hands of a Receiver. The result of that would be that the concern would be shipwrecked and any prospects that there might be of bringing the Company round and realising its assets would be destroyed. His only objection to the appointment of the committee in the manner proposed was, that the result of their investigations would not be known for three months; and within that time the concern would be shipwrecked, as there was no money to pay their creditors.

Lieut.-General Sir J. STOKES endorsed the remarks of Mr. Pope, and said there was no doubt that the Directors desired nothing better than a thorough examination of their acts. The delay of such an investigation as was now proposed would, however, be fatal to the existence of the Company, as money must be found within a few days to keep things going.

Mr. F. L. RAWSON (Managing Director) said that he held over £30,000 in the shares of the Company, and he had also been the largest shareholder in the other companies. He was bound to give them the best of his abilities, and he could receive nothing until 15 per cent was paid on the ordinary share capital. Unless the thing went right, he got nothing. He agreed with Mr. Pope, that no exception could be taken to what the shareholders had said. The other committee which had been alluded to came to the same conclusion as the Board—that it was necessary to find a certain amount of money immediately to prevent the creditors from stepping in. He would do his utmost to work for the shareholders for nothing, until their affairs had been placed in a proper condition. As Managing Director he must take the responsibility of the position, but there were certain events which mitigated the blame which one had to carry. He attended to what was called the financial portion of the business—the buying and selling, the investigating and the developing of patents; but the industrial portion of the business had been caried on by others, although he must be held nominally responsible for the results. They had been deceived as to the Kidsgrove business. The industrial portion of the business had not had the management which it should have had; and when they found out the mistake that had been made in this direction they appointed the best man they could, and he had been conducting the business energetically, and cutting off losses very deeply. With reference to the industrial portion of the business it would pay its way and make a profit. The ordinary shareholders could not expect to make anything at all except by the particular department which he looked after—the new inventions, patents, &c.—but in the past few years they had made very large sums from this source. There was no reason why, in about two years' time, they should not be able to do so again. The electrical business was advancing rapidly, and what they had to do was to carry on their business quietly, realise the shares they held, pay back any temporary loan they might now make from the proceeds, and wait for better times. The only reason they could find out why the Stock Exchange had refused them a quotation was that the old Woodhouse and Rawson Company (Limited) was not wound up, and that the purchase by this Company was not completed, whereas, in the opinion of the Directors, by the arrangement they made, they had thought that it was completed. They only approached the Committee once for a quotation. It had been stated that the call that was made shortly after the last meeting was not referred to at the meeting, but the fact was that the point was put on a slip of paper and handed to the Chairman to mention, but it was overlooked. He got up himself with the intention of mentioning it, but as the meeting rather "sat upon him," he sat down.

Mr. WHATELEY (a member of the Committee referred to) said that the conclusion which they arrived at, shortly, was that it would be positively suicidal to allow the Company to be wound up now; but that if it were not to be wound up, they must each and all of them find some money for it. He believed that about 10 per cent. of their holdings would do all that was required.

Mr. STUTCHBURY (the Manager) said he desired to impress upon them his honest opinion that there was no need for a scare, and they certainly knew the worst. He had found to his surprise that the loss on the trading—the real industrial trading—had not averaged more than £17,000 a year since they started. That might appear a large amount to some; but as a business man, and one connected for many years in engineering business, he regarded it more as so much money sunk with a view of building up their business. With a large lock-up of stock and investments they were at the present moment short of available funds; but apart from that he had no hesitation in saying that their position to-day was better than it had ever been. Their industrial business was surely but slowly gaining ground, and their reputation for good, sound, honest work was second to none. They were every day remedying the defects they had suffered from. In the last six or seven months he had effected savings amounting to £7,000 a year, and he could see his way to making a reduction in the coming year of a further £4,500

Lieut.-General STOKES observed that, as the Director who devoted most time to the industrial branch of the business, he could fully endorse what their Manager had said.

Mr. SQUIRE, after some further discussion, proposed the following:—

"*That a committee of consultation, consisting of five of the principal shareholders, with power to add to their number, be appointed to confer with the Directors as to the present position and future prospects of the Company, and to report to the shareholders at the earliest possible date, and also that the balance-sheet and statement of accounts from August 1 to December 31, 1892, be prepared under the supervision of the Committee, and submitted to a special meeting to be held as early as possible; further, that the consideration of the adoption of the report be deferred until the report of the Committee be received.*"

Mr. BACON said he would second the motion.

Mr. POPE again pointed out the necessity of further powers being given to the Directors to raise money, as their creditors would be all coming upon them insisting upon being paid.

The resolution, as proposed by Mr. Squire, was then put to the meeting, and agreed to, and a committee was appointed, consisting of Messrs. Squire, Whateley, Pilling, Bacon, W. Griffith, and General Fife.

After some further discussion relative to the amount which the Directors should be empowered to raise pending the report of the committee,

The CHAIRMAN proposed the following resolution:—

"*That the Directors be authorised to raise a sum not exceeding £20,000 on the security of the floating assets of the Company, and that for this purpose the limit of the borrowing powers conferred on the Directors under the Articles of Association be increased from £250,000 to £265,000.*"

Lieut.-General Sir J. STOKES seconded the resolution, which was adopted.

The Directors and auditors were re-elected by other resolutions; and the proceedings, which lasted four hours, terminated with a vote of thanks to the Chairman and the Board.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Town Hall and Parks Committee of the Burnley Town Council invite tenders for the supply and fixing of fittings for the electric light for the Town Hall, Burnley. Tenders must be addressed to the Chairman of the Committee on or before Wednesday, January 18th. Further particulars are given in our advertisement columns.

TENDERS ACCEPTED.—At the meeting of the London County Council on Tuesday, the Asylums Committee reported that they had considered the tenders for the second contract for the electric lighting (wiring, &c.) of Claybury Asylum. The lowest tender was that of Messrs. Appleton, Burbey, and Williamson, Queen Victoria-street, for £6,074, which they proposed should be accepted, subject to a supplemental estimate of £5,500 being submitted by the Finance Committee. The Committee had to point out that the sum of £17,500, authorised by the Council to be expended for the installation of the electric light, would not be sufficient to cover the whole cost of the work. The original estimate did not include the lighting of the mansion-house, since determined upon at an estimated cost of £1,500, nor certain necessary additional lights in the various workshops at an estimated cost of £600. The contract of Messrs. Latimer Clark, Muirhead, and Co. for the engines, dynamos, &c. (already entered into), amounted to £15,130, and with the above-mentioned tender of £6,074 would make a total sum of £21,204, or about £3,700 in excess of the £17,500 authorised. The excess was partly due to the extra lighting above-mentioned, and the remainder to the fact that all contracts were now proving to be higher than the estimates. A further sum of £1,800 was also required to cover commission to architect, salaries of clerks of works, and any contingencies. This would increase the first estimate by £5,500. The recommendation of the Committee was agreed to. The list of tenders sent in appeared in *The Electrician* of the 9th inst.

——— Messrs. Reed, Blight, and Co., have secured the contract for lighting Arundel Castle, Sussex, for the Duke of Norfolk. Mr. A. L. Phillips is the consulting engineer.

MESSRS. W. T. GOOLDEN AND CO.—This firm write us that, owing to the large extension in their electric mining and manufacturing business, they have decided to transfer their installation and fittings branch, from January 1, 1893, to their late manager. Mr. W. E. Townsend, of the firm of Messrs. Townsend and McIntyre, of 19, Brook-street, W., informs us that they have opened a showroom, at that address, for electric light and other fittings, and in order to carry on the installation business taken over from Messrs. Goolden and Co.

NEWTON ELECTRICAL ENGINEERING WORKS.—The well-known Taunton dynamo and other electrical apparatus are well illustrated in a catalogue which has been issued by this firm. The various sizes of dynamos, and the output which they will give at various speeds, are clearly set out in tables.

MACHINERY, TOOLS AND ENGINEERS' STORES.—Mr. George Hatch has issued a very useful price list of engineers' tools, bolts and nuts, machine tools and contractors' stores. We notice a large variety of drilling machines and shaping machines for both light and heavy work. The contents are excellently illustrated and contain very full descriptions, including, in many cases, weights, measurements and descriptive details. A considerable number of tools for special trades are to be found in this high-class catalogue.

Hosted by Google

MESSRS. JOHN SHAW AND CO.—Price lists Nos. 1 and 2 relating to the manufactures of this firm are to hand, and include illustrations and prices of a large variety of spigot and faucet pipes, turned and bored pipes and connections, manhole covers, surface boxes, &c.

MESSRS. LISTER AND CO.—This firm send us their latest illustrated list of milling machines, which is accompanied by some useful notes on the working of the machines, a table of speeds, pitches, &c.

MESSRS. SMITH AND GRACE.—This firm have just issued a price list of their new patent independent grip shaft couplings for which advantages are claimed that it is in one piece, that no keys are required, and that there are no projections.

A DIRECTORY OF CONTRACTORS.—A useful Directory of Contractors for public works is issued by the proprietors of the *Contractors' Chronicle*, an old-established journal, giving weekly the latest particulars of open contracts, results of tenders, and similar information. The Directory contains a mass of information which will be found of service to electric light supply makers and dealers, machinery builders, &c.

CALENDARS FOR 1893.—Sir Joseph Causton and Sons send us a useful hanging calendar of handsome design. —— Messrs. Badoureau and Jones, electrotypers, send us a calendar illustrating the process of boxwood block making, stereotyping, electrotyping, &c.——The Western Electrical Company forward a calendar, consisting of a well-executed photograph of their stand at the Crystal Palace Exhibition, with the calendar in the mount of the photograph. The idea is a good one.——Messrs. Minter Bros. issue a neat hanging calendar, with a thermometer attached.

SHIP LIGHTING.—Two new vessels are being built for the Cunard Company, to be called the "Campania" and the "Lucania," and Messrs. Siemens Brothers and Co. are completing an extensive installation of the electric light upon each vessel. Four sets of generating plant are supplied to each steamer, consisting of Siemens' dynamos, coupled direct to Belliss engines, and capable of supplying 1,350 16-c.p. lamps, including 8 large groups of 8 lights each, for cargo working, and a powerful search-light. The switchboard consists of 13 sections, so arranged as to be capable of connecting up any of the four dynamos installed. The supervision of this important installation has been undertaken by Dr. J. T. Bottomley, F.R.S.

PERSONAL.—We are requested to state that the only connection between the firm of Messrs. Smeeton and Page and the General Electric Company is that of customer and dealer.

AWARDS.—Messrs. John Davis and Son have been awarded two gold, three silver, and one bronze medal for their exhibits at the Kimberley Exhibition.

——— Messrs. Mather and Platt (Limited) have received four gold medals for their exhibits at the South African and International Exhibition– one for dynamos for electric lighting and the electrical transmission of power, another for electric lighting plant, a third for incandescent lighting plant, and a fourth for motors.

THE BRUSH COMPANY.—*Money* understands that negotiations are pending between the Brush Electric Light Company and the South-Eastern Railway Company, concerning the acquisition by the latter of the extensive works of the former in Belvedere-road, Lambeth.

MESSRS. POOLE AND WHITE (LIMITED).—A statement of affairs has been issued in reference to the winding-up of this concern. The gross liabilities as to creditors are returned at £23,293, against which £10,104 is expected to rank for dividend. As regards contributories, the total deficiency is £16,082. Referring to *The Electrician*, it will be seen that the Company was registered in February, 1890, to carry on the business established by Messrs. T. G. Poole and W. White, at Nos. 58 and 59, Bread street, E.C. The business was afterwards extended, and premises have from time to time been taken at King's-road, Camden-Town, N.W.; No. 10, Glasshouse-street, W.; and 27, Arcade-chambers, Manchester. The nominal capital is £20,000, divided in 3,400 ordinary and 600 deferred shares of £5 each. On July 22, 1892, Mr. W. J. Kelly was appointed receiver for the debenture holders, and the assets of the Company are at present being dealt with by him. There are 172 creditors, 201 debtors, and 40 contributories. Mr. C. J. Stewart, official receiver and provisional liquidator, concludes his observations on the winding-up with the following remarks:—"It may be noted that the whole of the assets have been put beyond the reach of the ordinary creditors within the last twelve months, except in the case of one 'fully-secured' creditor, whose mortgage for £1,000 is stated to have been given in 1890." The first meeting of creditors was held at the Inns of Court Hotel, W.C., yesterday (Thursday), when the Official Receiver presided. Mr. Tryon dealt at some length with the working of the Company from its incorporation, and his own interests in the concern, and complained that he had been misled as to the state of some of the accounts, and that he had done all he possibly could in the interests of the firm and the creditors and shareholders. Mr. Poole said that the concern had largely suffered from want of ready money. Mr. Street (representing the International Okonite Company, Limited, and Messrs. Bullers, Limited) proposed that Mr. E. Wylie, of Bloomsbury-mansions, W.C., be appointed liquidator, which was unanimously agreed to. It was also decided that a committee of investigation be appointed with a view to reconstruction. Mr. Street put forward the names of Messrs. Thorp, Vaughan-Stevens, Stedall, and Tryon, who were appointed. This left one nomination to make, which the Official Receiver suggested should be made at the meeting of shareholders, a proposal which received unanimous support.

MR. RANKIN KENNEDY.—The first dividend in the estate of Mr. Rankin Kennedy, late of the Carntyre Electric Works, will be paid at Messrs. Dunlop and Murray's, 82, West Regent-street, Glasgow, on and after the 27th prox.

POLYTECHNIC.—The next term of the Polytechnic School of Engineering in Regent-street will start on Monday, January 16th, and special facilities are offered to students in the course of Electrical, Civil, Marine, and Colonial Engineering.

THE CHRISTMAS POSTAL ARRANGEMENTS.—There is to be no delivery in London or the suburbs on Christmas Day. The arrangements will be as on the ordinary Sunday, and the Postmaster-General has issued a circular detailing special arrangements for Boxing Day, December 26th, in reference to letters, telegrams, parcel post, and express delivery.

BRIDGEND.—The Local Board have decided to apply for a Provisional Order at once, and will purchase lands and commence the construction of works for lighting the town with electricity.

BRISTOL.—At the last meeting of the Council the arrangement entered into with Messrs. W. H. Allen and Co. to execute the work previously undertaken by Messrs. Woodhouse and Rawson United (Limited), for the supply and erection of condensers, pumps, steam, and other pipes, was confirmed, and a resolution was adopted adding to the area of electric supply a district not included in the original Bristol Order of 1883.

BROMLEY (KENT).—The Clerk, at the last meeting of the Local Board, stated that the support offered to the electric lighting scheme was disappointing, and it was decided to make another effort to obtain subscribers.

BUCKINGHAM.—Extensive alterations are being made in the Buckingham Central Station by Messrs. Parr and Gillies, who have now taken over the working. A new central station, with a capacity of 1,500 8-c.p. lamps, is nearly completed.

CANTERBURY.—The Town Clerk states, in reference to the costs of transferring the Provisional Order to a local company, that the Company consider the cost of the transfer (about £410) excessive.

CHELSEA.—At the last meeting of the Vestry the clerk read a communication sent to the Board of Trade by the agents of the St. Luke's, Chelsea, Electric Lighting Company, and a member of the Vestry (Mr. Brass) suggested that it would be better for the Local Authority to deal with the electric lighting itself rather than pass it over to a private company.

CHRISTIANIA (NORWAY).—A company has been formed here to construct electric tramways in the city, six kilometres in length, at a cost of £2,300.

COURT OF COMMON COUNCIL (LONDON).—At the last meeting of the Council the report of the General Purposes Committee in reference to the payment of £607 odd for current supplied to the Mansion House by the City of London Electric Light Company, was read. Mr. Morton, M.P., asked whether the cost of the electric light was heavier than gas. The answer was, that in this case the cost was about double that of gas, but that as a set-off the decorations were in a better condition than they had ever been before.

DUBLIN.—In consequence of the malicious extinguishing of the electric light, to which we referred in our last issue, it was decided at a meeting of the Corporation, held on Monday last, to vigorously apply the section of the Electric Lighting Act of 1882, which renders any person guilty of tampering or injuring any electric line or work to a penalty of penal servitude not exceeding seven years, or with imprisonment with hard labour for any term not exceeding two years.

EALING.—The Local Board have agreed to the Electric Lighting Committee's recommendation that Messrs. Bramwell and Harris be invited to report upon a scheme for lighting the district, the report to be sent in by Jan. 21st next.

Hosted by Google

EDINBURGH.—Seven members appointed by the Town Council to visit the various centres of electric lighting activity south of the Tweed, are visiting London, Bournemouth, Cambridge, Bradford and Newcastle. The deputation includes the Lord Provost.

EDISON-SWAN WORKS.—In connection with the large works at Ponder's End, an application was made before the Licensing Committee for a licence for stage plays and for music and dancing, to be set apart by the Edison and Swan Company for the benefit of their employees. It was stated that the works employ about 750 persons. The licence was granted.

FLEETWOOD.—Mr. T. L. Miller, of Liverpool, has been appointed by the Fleetwood Commissioners to advise them upon the various tenders received for the electric lighting of the town.

HECKMONDWIKE.—Mr. S. Wood, Chairman of the Electric Lighting Committee, presented to the Local Board on Monday a report as to the proposed lighting of the town by electricity. The Committee recommend that the Board apply to the Board of Trade for permission to erect the necessary plant, &c., and to the Local Government Board for their sanction to supply the necessary capital to enable them to carry out the scheme, according to which a saving of £472 a year over the present charges for lighting is anticipated. The recommendation to the Committee was carried by a majority of one vote.

ILFORD.—The Local Board have decided to appoint an expert to advise them on the matter of introducing the electric light into Ilford.

IPSWICH.—The lighting plant of the Ipswich Electricity Supply Company (Limited) was disposed of on Monday by Messrs. Garrard, Turner and Son. We understand that the entire stock was purchased by Mr. Atthill (representing Messrs. Laurence, Scott, and Co.), Mr. Edey, Mr. Percy Huddleston, Messrs. Parr and Gillies, and the proprietors of the *East Anglian Daily Times*. The sale was stopped as soon as the amount necessary to satisfy the execution had been reached. The *East Anglian Daily Times*, in its issue of Saturday last, blames the Corporation for the part it has played in bringing about the failure of the Ipswich Electric Lighting Company, and mourns the return to gas lighting in terms which show that the electric light was thoroughly appreciated in Ipswich.

NANTWICH.—It has been decided by the Local Board to take the necessary steps to obtain powers under the Electric Lighting Act.

NEWPORT (MON.).—It has been decided to invite Prof. Robinson to Newport to advise the County Council on the subject of the electric lighting of the district, and to prepare a report, at a fee of fifty guineas.

NORTH BRIERLEY.—The Local Board has accepted the offer of Messrs. Waterhouse and Edmundson to defray half the cost and pay one halfpenny per hour for each lamp in an installation to be erected by that firm, with a recommendation that all poles and apparatus be removed at the request of the Board.

PAISLEY.—An endeavour is to be made to obtain an extension of time for carrying out the provisions of the Electric Lighting Order by the Town Council.

ST. AUSTELL.—At the last meeting of the Local Board it was decided to place a powerful electric lamp over the Fountain in George-street, St. Austell, the work to be done by Messrs. Veale and Co. (Limited), whose application for the renewal of their electric lighting licence for two years was also granted.

SUNDERLAND.—The Town Council have now decided to obtain the assistance of an expert to advise them in the selection of the best scheme for lighting the town by electricity. The Council will retain the Provisional Order obtained by them in 1890, and they have consulted with two electric light companies as to the terms for laying down plant and for running the same for a number of years; but too high a percentage of profit has been asked. The amount to be expended on preliminaries is not to exceed £200.

TAUNTON.—At a special meeting of the Town Council it was resolved to memorialise the Board of Trade for a Provisional Order for lighting the town and suburbs by electricity.

COMPANIES' MEETINGS & REPORTS.

The Electric Construction Corporation (Limited).

The fourth general meeting of this Corporation was held at Cannon-street Hotel, on the 16th inst., Sir Daniel Cooper, Bart., K.C.M.G., presiding.

The SECRETARY (Mr. W. Samson) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Three months ago I very reluctantly, at the entreaty of my colleagues, took the position of Chairman of this Corporation, and from the day I have held office until now my best endeavours have been to re-establish the credit of the Corporation. I and my colleagues have stuck manfully to the ship, and have within a few weeks obtained for it a position it has never held since the day it commenced work. Since my election as Chairman the time for the Corporation has been a critical one, but the Directors, individually and collectively, have found money and credit so as to enable us to meet all demands, but to do this they have had to incur responsibilities which I do not think any other Board of Directors would have done; but their faith in the soundness of the Corporation, if well and carefully managed, is such that they felt themselves secure, and they also felt sure that the shareholders would appreciate their efforts. The Corporation when it started had to make its name, like all new companies, and had to obtain work at times under onerous conditions. The profits earned, therefore, should not be gauged as they would be for an old and established company. I may instance the works at Manchester-square, near Rathbone-place; the Overhead Railway at Liverpool; the Works at Oxford; and the South Staffordshire Tramways. These important orders have to a great extent given the Corporation a footing and a name in the trade, and are a guarantee for future orders, of which we have now, according to what Mr. Parker says, from £60,000 to £70,000 in view. When the name of the Corporation is established it will enable it to obtain contracts on more profitable terms. The experience, too, of the last three years, will enable the Board to manage and guide the business more firmly and economically. The shareholders, as a body, have not supported the Corporation as they ought to have done in the issue of the preference capital, and the Directors have had to find the means among themselves to carry on the Company, and, therefore, from their practical knowledge are convinced that it would be folly to declare a dividend. They now ask you to contribute towards the £100,000 Second Mortgage Debentures, and let the Directors have the satisfaction of seeing you help the Corporation in the way they themselves have done. Mr. Duncan has issued a circular from a sick bed, and I have no doubt that his notions are none of the brightest or strongest. I may instance his remarks about the Electrical Power Storage, which was taken by this Corporation at a large price. From the day it was taken over to the day it was leased to the present Company the turnover gradually dwindled, and if it had continued to be conducted by the Electric Construction Corporation, it would have vanished by this time; whereas, managed separately, it has regained in 12 months its old output and is still advancing, and this Corporation is receiving a sum of £9,000 a year as a minimum; and as it holds the bulk of the shares in the undertaking, it practically receives all that is made by the Electric Power Storage Company. A Mr. Dunnill, the holder of a few shares, has also issued a circular, which I hope that the shareholders will treat respectfully, but I trust that they will not be led away into a scare, and so destroy absolutely their property by statements that can be easily and conclusively answered. The present Directors, as I have said before, have done a great deal in a very short time to put the Company on a firm footing, and they hope with new blood to do much more during the year to concentrate the resources of the Company, and also to confine it to its legitimate work; but whilst they are doing this they must not be harassed by the shareholders themselves, through a Committee of Investigation, which would only have a most disastrous effect upon the credit and business of the Corporation, already seriously injured by the attacks of hostile shareholders. At the same time there is no desire on the part of the Directors to withhold any information which they can properly give to the shareholders. The shareholders appoint the auditors of the Company, Messrs Broads, Patteson and Co., who are most able, most painstaking, and most independent, and would not pass any transaction that was not strictly correct. I am informed by our legal adviser that Mr. Dunnill's resolution is out of order, and cannot be moved; but nevertheless it may not be out of place for me to state the conclusion the Directors have arrived at respecting it. In the first place, let me say that I myself hold as large an interest in the Corporation as the whole of the shareholders whose proxies Mr. Dunnill has obtained. I merely mention this to show that the Board have a very substantial interest in the property of the Corporation. The Directors have carefully considered the proposal for the appointment of a Committee in the resolution embodied in Mr. Dunnill's circular, and came to the conclusion that there were very grave objections to a Committee. The Directors of the Board, as now constituted, have nothing whatever to conceal; and, if they considered only their own feelings, would welcome the appointment of a committee, but they are perfectly satisfied that the appointment of this committee would be exceedingly detrimental to the interests of the Corporation. Of this I may just give you an example. A foreign contract which they had good hopes of securing has gone past the Corporation, on the statement by the gentleman who had its disposal, that the rumours prevalent respecting the Corporation, and suggestions of its inability to carry out the contract if they got it, had deterred him from offering it to the Corporation. The final settlement of a contract which the Corporation had hoped it had secured is now being suspended, waiting the result of this meeting, probably to see whether the Directors held the confidence of the shareholders, and the Corporation is in a position to carry out the contract. But altogether apart from these considerations, the Directors cannot see that the appointment of a committee or its report, could carry the weight with the shareholders of the examination into the affairs of the Corporation which has just been made by the Electric and General Investment Company. That company was not a shareholder of the Construction Corporation, and had no interest in its affairs. When a loan to the Company was proposed, it, as the report states, caused an exhaustive examination to be made of the books and accounts, and it had a report by an expert upon the works. The result is that they have agreed to provide £50,000, which, I may tell you, is absolutely necessary to carry on

Hosted by Google

the business of the Corporation. Surely these facts ought to carry more weight with the shareholders than the reports of ten committees. For these reasons the Directors have come to the conclusion that they must resist as most prejudicial, I will not say fatal, to the Corporation, the carrying of any such resolution as is indicated in Mr. Dunnill's circular. At the same time they must regard the passing of such a resolution as a vote of want of confidence in themselves. Gentlemen, I hope I have sufficiently impressed you with the gravity of the issue as affecting the future of the Corporation. As I am suffering from a severe cold, the Vice-Chairman will now explain to you the figures of the balance-sheet, with which he, from his active participation lately in the affairs of the Company, is better able to do than I am. I beg now to move:—

"*That the report of the Directors, and the accounts annexed thereto, be, and the same are, hereby adopted.*"

Mr. J. IRVING COURTENAY (Vice-Chairman): I respond with pleasure to the call of the Chairman (Sir Daniel Cooper), who has so gallantly come to the assistance of the Corporation under the trying circumstances with which you are all more or less acquainted. I feel bound to state that this Corporation owes a deep debt of gratitude for the splendid financial support given it by Sir Daniel Cooper, who has been loyally aided by the present Directors. I now propose to go through the profit and loss account and balance-sheet, and offer such explanations as may seem necessary. Taking the profit and loss account first, the head office expenses, viz., £7,870 3s. 1d., are less than they were last year by £3,553 4s., which I think you will agree is a substantial reduction, and the Directors intend to still further reduce these expenses. The amounts under the head of "Special Expenses" are very heavy, but the bulk of them may be deemed to be exceptional, and not likely to occur again; for instance, the chief amount in the allowances on contracts arose in the final settlement of accounts, in regard to one contract—namely, that with the Metropolitan Electric Supply Company, Limited. There were questions of vibration and other legal questions involved, and in the opinion of those who know the question best, the arrangement come to was a beneficial one for both parties interested. We are indebted for this friendly arrangement to the kind offices of Sir Henry Mance and Sir John Pender. Another amount is for commission paid to the British Electro-Chemical Agency (one of the subsidiary companies) in consideration of a licence for some of their patents which were essential for the proper working of patents which were sold by this Corporation to the Phosphorus Company (Limited). The Electric Construction Corporation has a very considerable interest in the Electro-Chemical Agency. The last item of these "special expenses" is for outlay in connection with the Crystal Palace Exhibition. The Corporation is bound to make a good display at Electrical Exhibitions, but following years benefit by the foundations thus laid for new business. The maintenance of patents has been a heavy account in the past year, owing to the costs incurred in the important case known as the "Lane-Fox Distribution Patent," which resulted in a judgment against Mr. Lane-Fox. This again is an expenditure the benefit of which will be felt in the future. We consider that some of the items under the head of "Special Expenses" might very fairly be chargeable to capital—at anyrate, not wholly charged against the revenue of one year; but I assume you will approve of the Board's action in writing off all these charges at once which has the effect of very greatly strengthening the balance-sheet. Turning now to the balance-sheet, you will observe an item of £6,470 for difference between par value of shares sold and amount realised, which we have deducted from the reserve account set apart for this purpose; and this is a convenient opportunity for me to call your attention to the principle the Board has adopted, with the approval of the auditors, which is, not to attempt to value the shares we hold in subsidiary companies at any other figure than their par value, but to create a large reserve fund as against them, so that when the shares are realised, should there be any deficiency, there will be an ample reserve to meet it. The reserve is independent of the £18,000 reserve for general purposes, and £10,000 for bad and doubtful debts. The amount of shares held by the Corporation has been the subject of comment, but you will remember that a large proportion of these shares were acquired in payment for various patents sold or licensed by the Corporation. We should, of course, have preferred to get cash, but that was not possible. It became necessary to develop and work the numerous patents owned by the Corporation, in some way or other and on the best terms we could get, and this remark applies also to the provisional orders. For legal and other reasons separate companies had to be formed, and we hope that, in future, these subsidiary companies will be a source of considerable income, the Corporation keeping itself to pushing and developing its manufacturing and contracting business, so far as practicable, upon cash terms only. You will have noted that there is a sum in cash, £3,115. 15s. 9d., at the London and General Bank (Limited), which is now in liquidation, of which £3,000 is on a joint deposit account on behalf of one of the subsidiary companies, as a guarantee fund in connection with patents sold to them. No official statement of the prospects of this liquidation has yet been made, but we are assured that no loss will accrue so far as this deposit is concerned. As stated in the report, the Directors do not propose that any dividend be paid on the ordinary shares for the past year, but recommend that the dividend, at the rate of 7 per cent. per annum, be paid on the preference shares to September 30th last, that £30,000 be placed to a suspense account, and that the balance of £26,862. 1s. 5d. be carried forward. The Directors believe this to be the sound course for men of business to take under existing circumstances, and that the shareholders will approve the policy. The Directors will use every effort to realise some of the shares, and to make the balance of profit and loss account available for dividend purposes as soon as possible; and though the fixed charges are somewhat heavy, I see no reason, with strict economy, both at Bushbury and head office, why a satisfactory dividend should not be regularly earned in the future. I now come to the work done at our Bushbury Works. The past year has been a very heavy one at the works. We have turned out an increase in the amount of work in our ordinary business, and have also put down a system of continuous current high-pressure distribution of electricity for Oxford, and during the Exhibition at the Crystal Palace we delivered by the same system about 500-H.P. over a mile into the Crystal Palace from the station. The Oxford installation, Mr. Parker says, has proved to be thoroughly efficient and reliable, and it will stand among the first of the installations in this country in the future as a means of supplying energy for lighting and power. We have also carried out the contract for the Liverpool Overhead Railway Company, or very nearly so, putting down the whole of their power in the electrical portion of the engineering, carriages, and all necessaries for running the line. This line of railroad is expected to be in running order about the end of the year. We have manufactured and installed seven and a-half miles of an overhead system of tramways for the South Staffordshire Tramways Company (Limited), which is now shortly to be opened for traffic. This work has been highly praised by the Board of Trade Inspector. These contracts have many novel features, and being the first of their kind do not admit of the profit that is to be made when regular business is established, but we may look forward to these being the pioneer enterprises of future great business in this class of work. The works are now thoroughly equipped, and their capacity can be largely extended with great advantage to the Corporation, as the additional charges upon additional business would be very much less in proportion. Mr. Parker tells us he knows of a substantial amount of work in different directions, which he expects will be entrusted to this Corporation to execute. The value of these contracts must not be gauged by the precise cash returns, but must be regarded rather as contained in the valuable advertisement from such important works as the Liverpool Overhead Railroad and the South Staffordshire Tramways. We have in the past year worked out in our laboratory several inventions for the more economical production of zinc, chlorine and alkalies; to carry some of these into practical effect the Directors have founded the Electro-Alkali Company. These inventions promise success in our laboratories, and I hope that Mr. Parker may in a short time be able to report that their commercial application is equally successful. The Alkali patents were in the first instance transferred with other patents to the Electro-Chemical Agency, but when as the result of full experiments, Mr. Parker arrived at the opinion that the alkali patents promised to be of great value, it was considered best to put them into a separate company, and they were bought back for preferred shares in the Alkali Company from the Chemical Agency, and they are now the property of the Alkali Company, in which the Electrical Construction Corporation has a very large interest. The Chairman has already dealt with the remarks of Mr. W. W. Duncan about the Electrical Power Storage Company, which are in some important particulars incorrect. The net profit when the Electrical Power Storage business was worked by the Electrical Construction Corporation, was never what Mr. Duncan states it was, nor are the annual costs of administration what he states; they are really about half the amount, because a portion of the account is for seventeen months' working, and a large sum is included for carriage, &c., which does not belong to administration account. I explained the figures to Mr. Duncan last autumn, when he remarked that my explanation had knocked the bottom out of his criticisms. He has thought fit to repeat them, but the reasons for his whole attack are obvious. Experience has shown that it is practically impossible to run successfully two businesses together which differ so much as do the storage battery and dynamo manufacturing business. The result is that, whereas the business had so seriously fallen off when it was worked by the Electrical Construction Corporation that it had nearly reached the point where no profit could be earned at all, we have, since it has been worked separately, nearly doubled the output, and are still increasing it. I think the shareholders would wish to hear further details from Mr. Parker of the important works I have alluded to, and later on I will ask him to address you. I now come to the important paragraph in the report dealing with the general financial position of the Corporation. I may state at the outset that the problem of how additional capital could be raised, on terms which would be satisfactory to the shareholders, presented some difficulties on account of the many interests which had to be protected. There are the First Mortgage Debenture Issues, at present of £150,000, then there are some preference shares, then come the ordinary shares, and finally there are the founders', whose rights have had to be safeguarded. I am glad, however, to be able to assure you that the scheme which the Electric and General Investment Company (Limited), after a very close study of the whole of the question (with the assistance of the most competent legal advice), has devised for us is one which protects and preserves the rights of all existing interests, and in this connection it is right, perhaps, to tell you that we have had an advantage in dealing with the Electric and General Investment Company (Limited) which we should probably not have had if the arrangements had been made with others, by reason of the fact that the Electric and General Investment Company have a special knowledge of this class of industrial undertakings, and they have, therefore, been better able to appreciate the great potentiality for future work which this Corporation possesses. The problem was, as to how £100,000 additional capital could be raised on terms which, while they are sufficiently attractive, are not unduly onerous to the Corporation, and the result is, I feel bound to say, to the satisfaction of your Board. We are raising £100,000 of new capital at a rate of interest of 6 per cent. per annum, which is no higher than the rate of interest paid upon your First Mortgage Debentures, and the scheme provides for this money to be repaid within a comparatively short period. Of course, it will be obvious to everyone that the money could not be raised on such exceedingly advantageous terms without offering a bonus, and the form in which this is done is satisfactory both from the point of view of the future of the Corporation, and also from that of the shareholders, who have the first right to subscribe the money. The bonus I speak of is given

Hosted by Google

in the form of an income bond which is attached to each debenture, and is of a corresponding amount, *i.e.*, the subscriber of every £10 Second Mortgage Debenture receives a bonus bond of £10 free of all liability, and this income bond will commence to carry interest from the date on which the debenture is drawn and paid off at par. The rate of interest will be determined for each year by the dividend paid on the ordinary shares of the Corporation for each preceding year. It is, perhaps, desirable that I should explain the procedure a little more fully by giving you an example. Assuming that at the end of next year debentures to the amount of, say £4,000 are paid off, then the income bonds to the amount of £4,000, corresponding to the debentures which had been drawn, will commence to carry interest, and they will receive interest for the year 1894 at the same rate as the dividend that may be paid upon the ordinary shares for the year 1893. I have no hesitation in saying that, in my opinion, these debentures with income bonds constitute an exceedingly profitable investment, but I hope to be able to convince you that the terms are not unduly onerous to the Corporation, because the Board feel that the new capital will of itself produce the amount which is required to pay the interest thereon and to redeem them; and if this expectation is realised, it will be seen that the Corporation will obtain the benefit of this increased earning power at the cost of merely the interest paid upon the income bonds On the other hand, the shareholders who subscribe for those debentures will make an exceedingly good thing, especially those whose bonds are drawn at an early date, because they will receive their principal back with 6 per cent. interest, and will at once rank with the ordinary shareholders for dividend without cost to themselves. This explanation of the scheme will, I think, make it clear to every shareholder that if he wants to secure the full benefit of the arrangement for himself he can do so by taking up his proportionate allotment. It is a great satisfaction to the Directors that the Board has been strengthened by the addition of the Right Hon. David Plunket and Mr. James W. Barclay, both of whom occupy so leading a position in the City of London, and with whose assistance the economies that must be effected in various directions, will be judiciously and effectively carried out, and we feel confident that, with the support of the shareholders, the Corporation can be made to take the first rank among the English, electrical properties of this country.

Mr. THOMAS PARKER supplemented the Vice-Chairman's remarks by a brief description of the various works in which the Corporation has been engaged. Amongst these, the most important have been the overhead railway at Liverpool—the largest practical effort in electrical railway work yet attempted—the South Staffordshire tramways, and the lighting of the City of Oxford.

Mr. H. P. DUNNILL (Ironbridge, Salop), who had given notice of a resolution to appoint a committee of seven shareholders to investigate the affairs of the Corporation, was informed by the Chairman that the resolution could not be put because the notice had been received 24 hours too late.

Mr. DUNNILL then moved the following amendment to the motion before the meeting:—

"*That the accounts be not adopted, that the Directors be requested to amend the same by giving all the particulars of all the shares in subsidiary companies, licences granted, and patents sold, and the amounts receivable in each case, and from whom, and that this meeting be adjourned to enable this to be done, and that fresh accounts be delivered to every shareholder seven days before the adjourned meeting.*"

He did not wish to say a word against the manufacturing business. If the Directors had employed the shareholders' money in legitimate work of that kind there would have been a good result; but it had been spent in exploiting companies and in paying promotion charges, and he thought that it was now necessary that a thorough investigation of their position should be made by independent shareholders.

Mr. W. U. COOK seconded the amendment, observing that it seemed ridiculous that they should have such a large capital and make so poor a return.

Mr. BEACHCROFT, representing a large holding in the Corporation, urged the shareholders not to pass the amendment, which, he said, was tantamount to a vote of censure on the Directors. There was all the more necessity, he maintained, for not taking such a step because the Corporation was approaching a period of successful operations.

Mr. HERRING explained the conditions under which the Electric and General Investment Company (Limited) has agreed to issue £100,000, additional capital for the further development of the business. He expressed his belief that the success of the Corporation in the future was certain with good management and greater economy.

Mr. DIBLEY, in reply to Mr. Millington, said that he would retire from the Board of Directors with the greatest pleasure if anything wrong could be proved against him.

After some remarks by Mr. HANCOCK with regard to the relations of the Electrical Power Storage Company and the Electric Construction Corporation,

Dr. DRYSDALE urged Mr. Dunnill to withdraw his amendment, adding that he had the greatest confidence in the Board, and that he was perhaps one of the few shareholders who had taken the trouble to see the works of the Corporation at Wolverhampton, which he described as being in every way excellent.

After some further discussion the Chairman put the amendment, which was lost by a large majority, only five voting for the amendment.

Mr. DUNNILL demanded a poll, but on being informed by the solicitor to the Corporation of the superior strength of the Board in the matter of proxies, agreed not to put the shareholders to the trouble of voting.

The original motion was then agreed to.

The CHAIRMAN proposed, and Mr. COURTENAY seconded, the re-election of the retiring Directors, Mr. James Pender and John B. Verity.

The motion was carried unanimously.

The auditors, Messrs. Broads, Patteson and Co., were, on the motion of Dr. Drysdale, seconded by a shareholder, unanimously reappointed.

Dr. DRYSDALE next proposed a vote of confidence in the Directors.

A SHAREHOLDER seconded the resolution, which was agreed to *nem. con.*

The CHAIRMAN returned thanks, and expressed the hope that at the next meeting he might have a more prosperous condition of affairs to report.

The proceedings then ended.

Crompton Electric Supply Company of Australia (Limited).

The third annual general meeting of the shareholders of the Crompton Electric Supply Company of Australia (Limited) was held at the registered offices of the Company, Mansion House-buildings, on Monday last, Mr. J. F. Albright presiding.

The SECRETARY (Mr. Francis Reeves) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen—You will infer from the notice that this meeting was convened because it is our duty to meet you before the end of this year, and we had hoped to be in a position to lay the accounts before you up to May 31, 1892, but unfortunately these have been delayed, and we have been expecting to receive them by almost every mail. I might, perhaps, explain that one of the chief reasons why the accounts and report from the other side have been delayed is that we ourselves in London have been in the past very stringent in endeavouring to see that the accounts were very satisfactory, so as to protect you interests, and we insisted on our auditors in Sydney going thoroughly into certain points, and the result, so far as this year's accounts are concerned, has been that the auditors have been extremely strict in respect to the right method of stock-taking. I have little doubt in my own mind that one of the other reasons is the one mentioned in one of our most recent mails from Sydney. One of our managers, Mr. Whiffen, has been unfortunately ill. I hope you will receive that as a sufficient explanation of the difficulty we have been placed in with regard to meeting you with the accounts. Speaking of Mr. Whiffen's illness brings me to another point with respect to our business, which I should like to comment upon. Seven or eight months ago we had the question of supplementing the management in Sydney brought very strongly before our notice, largely on account of the fact of Mr. Whiffen's ill health. This matter has received our most careful attention, and certainly my co-Directors have spared no pains—and I myself have done the best I could—to select the gentlemen we have sent out to Sydney to assist the management. We believe we have obtained an extremely suitable gentleman in Mr. R. H. Buchanan. About a fortnight ago we received a cable saying that he had arrived there, and we trust that he is now getting established in his position, and that we shall ere long receive the full benefit of his assistance. As most of you are well aware, business in the Australian Colonies for some time past has not been in a very flourishing condition. Any of you who have read the reports of other trading concerns connected with the Colonies will have seen this fact prominently dwelt upon; but although we anticipate that the accounts which we are now waiting for will also show to some extent this falling off in business, we are pleased to be able to report to you that our more recent advices give us considerable encouragement in regard to the revival of business—at any rate of the particular branch in which we are interested. There is another question which, as your Directors, we wish to bring before you. It has been very evident to us for some time past that the subscribed capital of the Company is insufficient to deal thoroughly and profitably with the whole of the business which the Company might have handled advantageously. Considerable contracts are lost for want of capital, and of course, as you all know, the business which is insufficiently strong in a financial direction cannot buy so cheaply or so well as if it had sufficient capital. Having carefully considered this question, the Directors have decided that the best way of supplementing the capital would be by the issue of debenture bonds, making a first charge on the Company's assets, and bearing interest at the rate of 7 per cent. per annum. These they propose to offer to the shareholders for subscription next month, giving the shareholders the first option of subscribing for them. It is, of course, almost needless for me to point out that if any shareholders wish to take up any more Ten per Cent. Preference Shares, which are the basis of our present capital, they can take that course. Further, with regard to this question of additional capital, we have felt the absolute necessity of increasing it, and we also feel that it is probable that it will not be such an issue as is likely to be taken up by any of the outside public. Therefore, we have to rely almost entirely on ourselves and personal friends of the shareholders for support in this matter. Whatever we may be able to do as Directors by getting personal support outside the present body of shareholders, I am not prepared at the present moment to forecast; but we wish it to be distinctly understood that the existing shareholders have this Debenture issue offered to them first, and it is only in the event of our not receiving sufficient support from them that we should attempt to get it subscribed for by people outside. So far, I have dealt with the question of the delay of the accounts, the supplemental management, and the issue of fresh capital. I now come to, perhaps, a rather pleasanter duty, so far as I am concerned, namely, to introduce to your notice Mr. Trotter, who is one of the Committee of Management in Sydney, and fortunately, I may say, for this Company, he has been able to come over to England on his own private business, and we are, therefore, in a position to receive the benefit of his visit by getting his advice in a way which we could not otherwise have done. Before

Hosted by Google

putting the resolution to the meeting, I would ask that gentleman to give you the benefit of the same information as he has given his colleagues.

Mr. TROTTER expressed the great pleasure he experienced in meeting the shareholders and to explain to them some of the work which had been successfully carried out by the Company. In the first place, he might say, as a shareholder, that he had the greatest faith in the future of their enterprise. Referring to the delay in receiving the accounts, he said that the auditors were puzzled to know what was meant by the points alluded to by the Chairman, and this, with other circumstances, led to greater delay in sending home the accounts. They must also remember that the distances in Australia were very great, and one of the reasons for the postponement was that a portion of the stock was some 1,500 miles from Sydney, viz, at Broken Hill, where, unfortunately, a great strike broke out which further increased the difficulty of delivering the accounts in time in London. He believed that Mr. Buchanan would be of great service to the Company. With regard to the business done in the past, he referred with satisfaction to the contracts carried out at Broken Hill Works, at the *Daily Telegraph* office, which is entirely lighted by electricity, and elsewhere. The installations had all proved satisfactory, and it would be gratifying to the shareholders to know that whatever work had been done by the Crompton Electric Supply Company, its name stood first for electrical work in the Australian Colonies. As to present and future work, they had taken the contract for lighting Perth, in Western Australia. They had in view also the lighting of Sydney, and were trying to get a Bill through Parliament for that purpose. It had already passed the second reading, but it took a long time to get a Bill through. As to the question of capital, this was a difficulty which he had seen for some time. The amount in the first instance was not sufficient, it being only about £13,000. The Broken Hill contract alone amounted to £3,000, or practically a quarter of the whole and if they were to do the class of work which they would be called on to perform they must increase the sinews of war. There were, of course, various schemes in sight within the scope of the Company, and it would be advantageous during the passing of their Bill through Parliament to have established a central station. But they did not see their way to do it. He mentioned this to show that, in numerous instances, if they had had the money they could have done better. He said again, unhesitatingly, that, as a shareholder and a member of the Committee, and with the help of Mr. Buchanan, he had every faith in the future of the Company.

Mr. T. R. TUFNELL agreed with Mr. Trotter in the soundness of the Company's property and its future possibilities. He hoped also that they might obtain the increase of capital asked. With regard to the question of the accounts he thought that the state of things was very unsatisfactory. Indeed, in this respect they seemed to go from bad to worse. This was the third annual meeting of the Company. On the first occasion they were told that the accounts would come forward, but in an imperfect state, so that they could be submitted to the shareholders for approval. Still, sufficient was shown to satisfy the Directors that they would be justified in declaring an interim dividend, which was accordingly declared. But now they were met with a bald statement that the accounts had not come forward, and therefore the meeting was to be adjourned, and in the notice calling the meeting there was no hint of a dividend. There was complete silence, although their financial year ended last May, and although the meeting was held two months later than previously, the Directors were not now in a position to tell the shareholders whether they had made a profit or loss by the last year's transaction. Mr. Trotter had told them of the extensive contracts which the Company had made, and it must be satisfactory to the shareholders to know that these contracts had been carried out satisfactorily ; but that gentleman had not pointed out what return had been realised by those contracts. At the last meeting he ventured to suggest that the difficulty in regard to the accounts might be obviated if the managers were requested to send home a transcript of the entries in their books month by month, as was done in other companies. Their auditors, although he had not the pleasure of knowing them except in connection with this Company, appeared to be most efficient accountants, and there would be no difficulty in satisfying these gentlemen as to the futility of their objections, if they had any, to comply with the orders of the Board on any question. He quite approved of sending out Mr. Buchanan, who seemed to be a most suitable person for the performance of the duties which would devolve upon him.

Mr. TROTTER said that there were difficulties in connection with getting in the accounts this year which were not likely to occur again.

Mr. TUFNELL thought that at least the Directors might have obtained sufficient information to satisfy them whether they had made or lost by the last year's transactions.

The CHAIRMAN said he was not the least surprised at the criticism just made. He pleaded guilty—not in his own private capacity, but for the Company. Their Directors had done everything in their power to obtain the information which they required, and he would ask the shareholders to again be patient, and to rest assured that the Board would do everything in their power to get over the difficulty. He moved :

"*That the Directors' proposal to issue First Mortgage Seven per Cent. Bonds to an amount not exceeding £10,000 be, and the same is hereby, adopted.*"

Mr. W. G. WHIFFEN seconded the motion, which was carried unanimously.

The CHAIRMAN next moved :

"*That this meeting be adjourned* sine die *to await the arrival of the accounts.*"

Mr. C. F. TUFNELL seconded the motion, which was carried.

Mr. T. R. TUFNELL proposed a vote of thanks to the Chairman and to Mr. Trotter, and the proceedings ended.

Morecambe Electric Light and Power Company (Limited).

The second ordinary meeting of the shareholders of the above Company was held on the 13th inst. at Morecambe, Mr. W. B. Hodgson presiding.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, said the duty was a pleasant one in view of the satisfactory result of the Company's first season's operations. Many difficulties had to be grappled with and overcome, but the various works had steadily progressed, and the installation increased and been perfected. The profit, £74. 9s. 11d., might seem small, but this was because of the greater cost in having to use the town gas instead of the "Dowson" gas, which they manufactured themselves, the plant for which could not be completed until October. The Chairman then gave a few particulars of the present financial position of the Company, from which it appeared that the amount expended on plant was £3,112, and the amount to pay £1,588, total £4,700 ; against which £2,870 had been subscribed in share capital, exclusive of the 760 shares accepted in lieu of cash, so that there remained a balance of £1,830 to be taken up in new shares. It would also be seen that debenture bonds for £1,000 had been issued, in order to partially make up for the deficiency in subscribed capital. He strongly impressed upon the shareholders the desirability of making an effort to subscribe for the £1,800 required among themselves, and thus increase their holding in what would ultimately prove a valuable property.

Mr. MABBOTT seconded the resolution, which was carried unanimously.

Mr. MABBOTT then moved that a dividend of 5 per cent. on the "called-up" paid share capital be declared, which was seconded by Mr. SCHOFIELD and adopted.

The Chairman of the Company, Mr. Morgan, having resigned his seat on the Board through inability to attend the meetings, Mr. Twyeroould was elected in his stead, and Messrs. W. Hollingworth and W. Wilson were also elected Directors. The auditor, Mr. J. Duff, was re-appointed.

It was decided that the accounts be made up in future to the end of December, and to hold the annual meetings in the first week of February each year, and after votes of thanks had been passed to the Chairman, the secretary, and the engineers, the meeting separated.

Woodhouse and Rawson United (Limited).

The following is the report for the year ended July 31, 1892, of the Directors of this Company. Contrary to our custom, we also give the balance-sheet issued by the Directors, and a print of the circular accompanying the report : —

The Directors express their regret that the favourable expectations which they entertained at the commencement of the year, and which they expressed in their last annual report, have not been realised. In common with almost all undertakings connected with electricity, your Company has felt severely the competition of the past year arising through the depression of trade, and this depression has told even more heavily on this Company, because, acting on the manifest and frequently-expressed desire of the shareholders that the industrial side of their operations should be developed, the Board has, within the last eighteen months, formed branches in the chief centres of electrical enterprise throughout England and the Colonies. Many of these, as, for example, Sydney and Johannesberg, after some initial losses incident to their formation, have developed into promising undertakings, but the benefits likely to be derived from them do not show in the last year's balance-sheet.

The result of these developments has been shown by the fact that whereas the turnover of the industrial portion of the Company's business was, in the first year, £72,258, that of the second year was £126,015, and that of the year just concluded £151,121. On the other hand, the financial portion of the business, which has been repeatedly stated to the shareholders to be the most profitable, has, owing to the financial depression, been almost entirely suspended during the past year.

In most of the Company's branches there has been a loss more or less serious, due to a large extent to the unfavourable period which succeeded their formation. Owing to the number of these branches the aggregate of such losses would in any case have proved large, but some are so considerable as to require special notice.

The failure of the arrangement for continuing the manufacture of incandescent lamps under the licence of the British Electric Lighting Company, obliged the Board during the past year to close down, at any rate for a time, a large portion of the Cadby Hall factory, which had been laid out for the purpose of this part of their business, and has also obliged them, as they are no longer at liberty to sell their lamps in the United Kingdom, to write down the value of their large stock by 75 per cent., the sale price of lamps abroad being only one-fourth of that realised in this country. Their valuable lamp plant has also depreciated largely from the same cause, as it cannot be utilised before the expiration of the Edison and Swan patent in November next. This has been one of the most serious blows to the progress of the Company, but one which may be retrieved when they recover at that date the right of using their valuable patents, which have gained for the Woodhouse and Rawson incandescent lamp an established reputation throughout the world.

The Board would point out another serious disappointment in the industrial department during the past year. When the Directors last met the shareholders they had obtained a valuable concession for lighting a large area of the richest part of Paris and had entered into an agreement whereby they had secured the co-operation of one of the strongest firms in France, who undertook to provide over one-half of the capital required. This would not only have provided a large profit by the sale of the concession, but would have furnished employment for the Company's works for some time to come. But owing to the insuperable difficulty experienced in raising the required balance of capital in this country, the advantages accruing to this Company by the concession were lost.

Hosted by Google

The newly acquired Kidsgrove and Chiswick Works have also been the source of unexpected losses. In the latter case the Board have reduced expenses to a mere nominal amount. The loss on the Kidsgrove Works was mainly incurred in realising the assets and carrying out the contracts taken over from the vendors. These contracts are now finished, and the works have been placed under capable management; they require only a sufficiency of capital to enable them to carry on an important and profitable business. The remainder of the loss is largely due to the large amount written off for depreciation of stock, which had been increased in the expectation of a demand which, unfortunately, did not arise.

The union of Cadby Hall and Manchester under one management has proved most unsatisfactory; the Directors have, therefore, recently placed the works at Manchester under the separate management of tried and experienced officials of the Company, and are reducing the business at Cadby Hall Works to the execution of contracts in hand and actual orders, with a correspondingly large reduction of staff and standing charges.

Notwithstanding, however, the serious check received by their industrial department through the causes above mentioned, the Directors consider that the Company would have to a great extent recouped itself by the results of its financial enterprise, if the past year had presented any opportunity for launching an industrial company with a reasonable prospect of success. The Oncken Company, which their contract with the patentee obliged them to bring out by August 1st, yielded only shares as the profit of this Company, and these do not appear in the present balance-sheet.

The Epstein accumulator, which was introduced by this Company, has proved a complete success as the most efficient and economical on the market. The Epstein Electric Accumulator Company, in which this Company is so largely interested, has been manufacturing now on a commercial scale for the past six months, and the result of its operations has been to demonstrate that the Epstein accumulator has solved the difficulty of using accumulators for traction purposes. Owing, however, to the general financial position there has been no chance of realising the value of the Epstein patents, but it is expected that this Company will derive large profits from them in the future.

The Directors are glad to be able to state that the reputation of the Company is such that inventions of the most valuable description are constantly placed in the Company's hands for development, a share of the patents being given for their services in this respect, and without any money payment on their part

During the last twelve months the Board have given unceasing attention to the reduction of expenses, and they are glad to be able to state that their efforts have been successful. It is anticipated that a considerable further reduction will be effected within the next three months. The Directors have relinquished their fees since last January.

The Directors regret to say that Mr. Philip Rawson was ordered by his medical adviser to abstain from all business for a time, and resigned his seat on the Board in September last; Sir Edward Thornton also at a recent date requested the Directors to accept his resignation. Your Directors have not filled up the vacancies occasioned by these resignations, for they have felt that it was due to the shareholders that the appointment of Directors should be such as might commend itself not merely to the Directors themselves, but to the general body of shareholders.

The auditors, Messrs. Jackson, Pixley, Husey, Browning and Co., retire in accordance with the Articles of Association, and offer themselves for re-election.

WOODHOUSE AND RAWSON UNITED (LIMITED).

We have examined the above profit and loss account and balance-sheet for the year ended July 31, 1892, but as we consider it desirable to refer to many of the items contained therein, we have made a special report to the shareholders, which report must be considered as part of this certificate.

JACKSON, PIXLEY, BROWNING, HUSEY and Co.,
Chartered Accountants, Auditors.

58, Coleman-street, London, E.C., December 12, 1892.

The following is a copy of the notice sent out with the report:—

"Notice is hereby given that the fourth ordinary general meeting of Woodhouse and Rawson United (Limited) will be held at the Cannon-

Hosted by Google

street Hotel, Cannon-street, London, E.C., on Thursday, December 22, 1892, at 12 o'clock in the forenoon, for the purpose of transacting the ordinary business of the Company, and, if thought fit, extending the limit of the borrowing powers of the Directors under the Articles of Association to such sum as may be determined.

"The transfer books and register numbers of the Company willbe closed from Wednesday, the 14th, to Wednesday, the 28th December, both days inclusive.

"By order, A. L. FOLEY, Secretary.

"88, Queen Victoria-street, London, E.C.
"December 13, 1892."

Gulcher (New) Electric Light and Power Company (Limited).

The report of the Directors of this Company for the twelve months ended June 30th last, is brief, and chiefly consists of a lament over the loss of £6,000 for the financial year. This is partially ascribed to depression of trade, and otherwise to "some contracts of an unfortunate character" entered into by the Company. The auditor's endorsement to the accounts which accompany the report is as follows: —

"I have examined the accounts of the Company, and the above balance-sheet, so far as the English accounts are concerned, correctly sets out the position of the Company on June 30, 1892. Vouchers for the items N. Z. stores and book debts, £2,932. 11s., have not been produced, and for these items I have been obliged to accept estimates furnished by the Chairman. —RUSSELL DAY, Auditor."

Yorkshire House-to-House Electricity Company (Limited).

The following report of the Directors to June 30th last is to be presented to the ordinary general meeting of the Company to be held on Wednesday next at the Great Northern Hotel, Leeds, at 2:30 :—

A freehold estate in Whitehall Road, Leeds, immediately behind the Great Northern Railway Station Hotel, containing upwards of an acre, admirably adapted for the Company's purposes, and having the advantage of a river frontage, has been purchased. The property includes several workshops and other buildings which are not at present required by the Company, and from which a rental is being derived. The erection of works has been vigorously pushed forward, but it has been found impossible to complete them as soon as was expected, and it will probably be early in the coming year before they are in operation. Underground culverts, about 10,000 yards in length, for the reception of distributing cables, have been laid, and the drawing in of the cables is now in rapid progress. An arrangement was made with the Highways Committee of the Leeds County Council for the necessary trenching to be undertaken by their staff, by whom the work has been admirably and expeditiously done.

The applications for supply of current already received are sufficiently numerous to lead the Directors to anticipate a successful business for the Company.

The whole of the present Directors having been appointed under Article 77, their appointment will require confirmation by the shareholders. The retiring Directors, Mr. Grosvenor Talbot and Mr. Robert William Eddison, being eligible, offer themselves for re-election. Mr. John Gordon, junior, offers himself for election by the Company as auditor.

NEW COMPANIES, STATUTORY RETURNS, &c.

ASKWITH AND CO. (LIMITED).—This Company was registered on the 13th inst., with a capital of £20,000 in £1 shares, to acquire, develop, and turn to account certain grants in Africa and elsewhere, and to carry on the business of an electric company in all or any of its branches, including that of electricians, electrical and mechanical engineers, electrical contractors, suppliers of electricity for the purposes of light, heat motive power, or otherwise, and manufacturers of and dealers in all apparatus or things required for, or capable of being used in connection with, the generation, distribution, supply, accumulation and employment of electricity.

HOCKET (LIMITED).—This Company was registered on the 15th inst., with a capital of £10,000 in £1 shares. The objects are—to adopt and carry into effect an agreement dated December 15, 1892, between Percival Everitt on the one part and Herbert H. Preece (on behalf of the Company) of the other part, and to carry on the business of electrical engineers, machinists, iron and brass founders, &c.

MEASURES BROTHERS (LIMITED).—This Company was registered on the 19th inst., with a capital of £100,000, in £100 shares, to acquire, take over as a going concern, and carry on the business of girder makers, iron and brass founders, bridge builders, mechanical and electrical engineers, machine and engineering tool makers, &c., carried on under the style or firm of "Measures Brothers," at 57, Southwark-street, London, S.E.

TAVY IRON AND ENGINEERING WORKS (LIMITED).—This Company was registered on the 19th inst., with a capital of £10,000, in £5 shares, to carry on the business (*inter alia*) of electrical and mechanical engineers, electricians, contractors for the supply of electric light, heat, and motive power and manufacturers of, and dealers in cables, wires, lines, dynamos, accumulators, meters, generators, fittings, brackets, lamps, globes, posts, insulators, and all things and apparatus necessary for, or capable of being used in connection with, the generation, distribution, supply, accumulation, and employment of electricity.

ELECTRIC CLOCK COMPANY (LIMITED).—The statutory return of this Company, made up to Oct. 27, 1892, was filed on the next day. Only 7 ordinary shares of a capital of £1,200, divided into 1,170 ordinary and 30 founders' shares, have been taken up, and no calls made, the original signatories being the only shareholders. No agreements, contracts, or registered office, have been filed.

ELECTRIC CYCLE SYNDICATE (LIMITED).—The statutory return of this Company, made up to Aug. 13th, was filed on Dec. 3rd ; 1,921 shares of £1 each, out of a total of 3,000, have been taken up. Upon 921 of these 10s. per share has been called, resulting in the payment of £380. 10s., and leaving £80 in arrears. In accordance with an agreement, dated April 25, 1892, Villeroy C. Doubleday has been allotted 1,000 shares of £1 each, each considered as fully paid.

ELECTRIC LAMP COMPANY (LIMITED).—The statutory return of this Company, made up to Nov. 10, 1892, has been filed. 2,797, out of a total of 4,000 shares of £1 each, on 107 of which the full amount has been called, resulting in the payment of £50, and leaving £57 unpaid. The remaining 2,690 shares have been issued as fully paid, in accordance with an agreement dated June 30, 1892, with Thomas P. C. Crampton, of 12, Swinton-street, Gray's-inn, London, W.C., and Albert Essinger, of 26, Thavies Inn, Holborn, W.C., by which they sold inventions of improvements in electric arc lamps, and also for an improved form of carbon, patents for which had been, or were about to be, granted in Great Britain, France, Austria, Italy, Spain, Belgium, Germany, and the United States of America, for £3,000, in £1 shares.

ELECTRICAL COMPANY (LIMITED).—The statutory return of the above-named Company, made up to Nov. 25, 1892, has been filed. The whole capital of £15,000, in 3,000 shares of £5 each, has been taken up, and £1 called and paid on each share. In addition to this, these shares were issued with £3 considered as paid upon each, in accordance with an agreement, dated July 25, 1892, with Key's Electric Company (Limited) and Frederick T. Eggers, its general manager and liquidator, by which that Company sold its business for £9,000, payable as above.

KENSINGTON COURT ELECTRIC LIGHTING COMPANY (LIMITED).—A meeting of this Company (in voluntary liquidation) is to be held at 1, Great George-street, Westminster, on January 19, 1893, at 5 p.m., to receive an account of the winding up.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's Four per Cent. Mortgage Debentures to bearer, due on the 1st prox., will be paid on and after the 2nd prox., at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, E.C. The coupons must be left at the bank three clear days for examination. The warrants in payment of the interest of the registered debentures will be sent out on the 31st inst., and the register will be closed from the 27th to the 31st inst. inclusive.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given in our advertisement columns that the coupons on this Company's second issue of Five per Cent. Debentures, due 31st inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the above bank three clear days for examination.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended December 18th were £918, as against £788 for the corresponding period of last year, being an increase of £130. The total receipts for half-year amount to £20,657, against £18,586 in the corresponding period of 1891, being an increase of £2,071.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—It will be seen by our advertisement columns that the share register of this Company will be closed from the 7th to the 14th January prox., both days inclusive.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LTD.).—We understand that the 10 per cent. dividend warrants on the preference share capital for the six months ending 1st ult. have been posted.

GENERAL ELECTRIC COMPANY.—The General Electric Company (Edison-Thomson-Houston Company) has just declared its semi-annual dividend of 3 per cent. on its Preferred Stock ; this is payable January 2, 1893.

HUMPHREYS (LIMITED).—A dividend of 7 per cent. on the Preference and 10 per cent. on the Ordinary stock of this Company has been declared, and £5,000 has been carried to the reserve account. The Directors' report states that this, the first year's trading, has been of a most satisfactory description.

SCOTTISH HOUSE TO HOUSE ELECTRICITY COMPANY (LIMITED).—This Company are inviting capital.

Hosted by Google

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The Stock Exchange Committee have been requested to allow £100,000 Four per Cent. Guranteed Debentures to be quoted in the Official List.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The coupons due 31st inst. on the debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street. Coupons should be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Dec. 16, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited) were £3,387.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended December 16th were £2,511, as compared with £2,544 for the corresponding period of last year.

ORDER AT ONCE.

"THE ELECTRICIAN" BLUE BOOK.

MORE THAN 1,000 PAGES OF RELIABLE MATTER. THE ONLY COMPLETE ELECTRICAL DIRECTORY.

"THE ELECTRICIAN"

Electrical Trades' Directory

AND

HANDBOOK FOR 1893.

SPECIAL NOTICE.

"The Electrician" Directory is published earlier in the year than any similar book, and therefore intending Subscribers and Advertisers are desired to send on their orders for Subscription Copies and Advertisements **at once.**

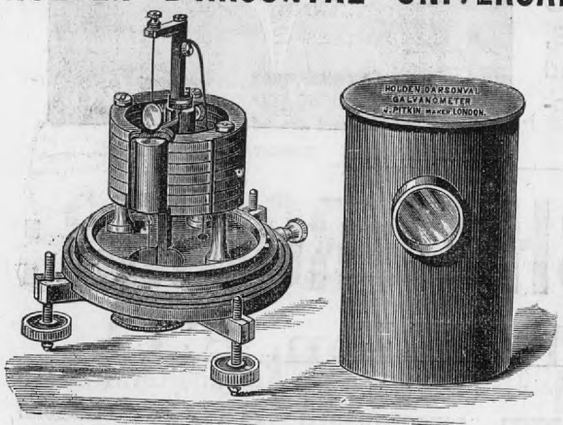
"The Electrician" Directory is the only Electrical Directory which gives all the most Reliable and Valuable Information relating to the Electrical and Kindred Trades. Only the Latest Information is included in the Book.

New Firms and intending Subscribers and Advertisers can be supplied with printed Circulars, giving full information relating to the well-known **Blue Book,** post free on request to any part of the world. Continental firms can be supplied with Circulars in French and German on request.

Several New Features will be introduced in the 1893 Edition, and all the original well-known Tables and Statistics will be brought quite up to date.

"THE ELECTRICIAN" PRINTING AND PUBLISHING CO., LTD.

HOLDEN D'ARSONVAL UNIVERSAL DEAD BEAT REFLECTING GALVANOMETER.



INSTRUMENT WITH COVER OFF.

As supplied complete with Three Coils, Shunts, Resistances, and Self-locking Key, it is

The Best Galvanometer for Zero Testing.
The Best Galvanometer for Direct Measurements.
The Best Galvanometer for Measuring Large or Small Currents by the Shunt Method, from 1 to 1,000 Amperes.
The Best Galvanometer for Measuring E.M.F. from ·001 to 100 Volts.

Prof. W. AYRTON, Pres. I.E.E., speaking at the Institution on 26th Nov., 1891, said:—"*The deflection is larger than we have obtained with any other D'Arsonval of anything like the same size. . . . . Many times as sensitive as the Carpentier pattern for the same periodic time and resistance of coil. . . . . The method of construction has the great convenience that the coil, with its top and bottom supports, can be at once bodily withdrawn. . . . . .*"

As supplied to H.M. Govt.; The Central Institution; City Guilds; Electrical School Chatham; R.A. College; Yorkshire College, &c.; and to Prof. Ayrton, F.R.S.; Prof. Fleming, F.R.S.; Sir T. Bazley, Mr. J. W. Swan, and many others.

Circulars, with all information, from the SOLE MANUFACTURER,

MAGNETIC INDUCTION IN IRON AND OTHER METALS.

By J. A. EWING, M.A., B.Sc., &c.

After an introductory chapter, which attempts to explain the fundamental ideas and the terminology, an account is given of the methods which are usually employed to measure the magnetic quality of metals. Examples are then quoted showing the results of such measurements for various specimens of iron, steel, nickel, and cobalt. A chapter on Magnetic Hysteresis follows, and then the distinctive features of induction by very weak and by very strong magnetic forces are separately described, with further description of experimental methods, and with additional numerical results. The influence of Temperature and the influence of Stress are next discussed. The conception of the Magnetic Circuit is then explained, and some account is given of experiments which are best elucidated by making use of this essentially modern method of treatment. The book concludes with a chapter on the Molecular Theory of Magnetic Induction; and the opportunity is taken to refer to a number of miscellaneous experimental facts, on which the molecular theory has an evident bearing.

Annual Subscription (U. K.), 19/6

NOTES.

What may perhaps be taken as the last attempt to overthrow the Edison lamp patent has just been defeated in the United States. After an unaccountable delay the Edison Company took proceedings, a few months back, against the makers of the well-known Sawyer-Mann lamp and obtained an injunction. Against this decision an appeal was immediately lodged, but without avail. The United States Circuit Court of Appeals held that the contention of the Westinghouse Company, the real defendants, that the General Electric Company, the real plaintiffs, were within the scope of the Anti-Trust law, had no bearing whatever upon the question at issue. The Appeal Court, however, in upholding the decision of the Court below, ordered the owners of the patent to supply lamps upon reasonable terms to electric lighting companies. The necessity for such a proviso, and several statements which have of late been current in the American technical press, would seem to point to a decided flaw in the patent law of the United States. The possession of a patent appears over there to carry with it an almost unlimited power of oppression.

The knotty problem of differential charges for electrical supply continues to be discussed in our Correspondence columns, and so far from finding a solution in the ingenious mechanical arrangements of the Scott meter, has thereby received at the hands of Prof. Garnett the addition of a delightful complication. In his letter this week Prof. Garnett suggests that instead of altering the rate of charge on the astronomical basis of sunset and a certain later hour in the evening, the rate should depend on the actual output of the station at any moment, and he arrives at the happy conclusion that the dials of the meters should register £. s. d. This irresistibly recalls the fact that the real object of electrical supply companies is not to provide electrical energy to the consumers, but dividends to their shareholders. The method of charging should, therefore, take into consideration the real value and cost of the dividend. The control of the station clock should then depend on the price of coal, of bread, of Consols, and of the company's shares, the rate of income tax, the bank rate, local rates, and the bimetallic ratio.

Although the discussion on earthing the middle wire, which has been aroused by the "Human Document" published in our issue of November 25, is not continued in our Correspondence column this week, we hope to print a further communication upon the subject, and to place before our readers rather more practical considerations than some of those which have already appeared. Meanwhile, the subject has been taken up in the columns of the *Review*, a contemporary devoted to insurance matters. On matters touching insurance, insurance experts should, of course, command attention; but we may be excused if we are less ready to accept than are they to offer their ideas on details of electrical engineering. Because the inventor of a system of concentric wiring has advocated earthing the middle wire, and with an obvious reason, amongst others perhaps, that owing to the large surface of his outer conductor external insulation would be very expensive, the *Review* jumps to the conclusion that concentric wiring involves earthing the middle wire. We are by no means prepared to advocate concentric wiring; it is still on its trial, and labours under two restrictions—patent rights and the necessity for special knowledge on the part of wiremen. It has received ample attention in these columns, and will doubtless make its way under the auspices of the two or three firms who hold patents for details. The subject of earthing the middle wire is of a much more important character. Those who are opposed to it are unfortunately the most reluctant to express their reasons, and talk with much vagueness—but, we must confess, with commendable caution—about corrosion and electrolysis, both of their own mains, and of gas and water pipes.

In describing the Holden hot-strip ammeter in *The Electrician*, Vol. XXIX., p. 589, we remarked that the available force in such an instrument is so great that mechanism might be introduced to correct the uneven division of the scale. In making this observation the question presented itself, why should a thermal ammeter exert more force than an ordinary electro-magnetic instrument? We did not allude to this apparent paradox at the time, but as the idea presented itself again in Mr. Arthur Wright's letter last week, we proposed the subject to Mr. E. T. Carter, who has attacked the problem in an article which will be found in another column. If a thermal ammeter jams, something will have to go, but the needle of a magnetic ammeter seems to enjoy sticking rather than otherwise. The mechanical work spent in an instrument of this kind is so small that attention is directed to force rather than energy, but it is here that the difficulty is concealed. A simple experiment might be arranged by taking

Hosted by Google

two long wires, similar in every respect, and hanging, say, a pound weight on one of them, and an ounce on the other. Pass the same current through the two, heating them, and causing them to extend. Now cut off the current, and one wire in retracting would appear to do more work than the other. The explanation put forward by Mr. CARTER, viz., the alteration of specific heats by tension or compression, accounts for a good deal, but several points remain somewhat obscure. As Mr. CARTER concludes his article with a couple of questions, we will end our Note with a few more. Will these two wires assume the same temperature? By how much is the resistance, and therefore the C^2R, affected by the difference in the tensions? As the pound does work in falling, will this appear as heat in the wire? And, finally, does one wire really do more work than the other?

WE have just received from Professor MACFARLANE a copy of a very able paper, entitled "The Principles of the Algebra of Physics." It consists of a modified version of the science of quaternions, and presents several new features of interest. The paper is a long one, for quaternions are so little used that, whenever they are discussed, the principles on which they are based have to be explained from the commencement. It has been said that quaternions have been of very little service in discovering new relations in physics, however convenient they may be for expressing old facts in a compact form; and with the view of removing this reproach various mathematicians have from time to time endeavoured to simplify the very cumbersome system of notation introduced by HAMILTON and TAIT. The latest attempt in this direction is that of Professor MACFARLANE, and his chief innovation consists in using the ordinary trigonometrical functions, with extended meanings, to represent certain relations between the different quantities used in the directional calculus. The result, however, is to make the mathematics assume the appearance of spherical trigonometry, and, as the symbols of ordinary algebra can be handled much more easily than combinations of sines, cosines, and tangents, we much doubt whether this departure is really a step in advance.

THE extension caused in a bar of iron when placed in a magnetic field was first shown by JOULE, and has been measured by various experimenters, the expansion being rendered visible either by an arrangement of levers, or with the aid of a microscope. A simple and elegant method of making the observations has, however, been recently used by M. ALPHONSE BERGET, and is described in the *Comptes Rendus*. The method is due originally to FIZEAU, who employed it for measuring the expansion of crystals, and the present modification is to fix the iron bar firmly at one end, and arrange so that the other end presses together two glass surfaces, such as the plane surface of a black glass mirror and that of a plano-convex lens. The interference fringes formed, owing to the phenomena of "thin plates," are displaced when the bar is magnetised, and from the amount of displacement the expansion of the bar can be measured. The results are excellent, for with an iron bar only 5 centimetres long it has been possible to obtain a curve connecting the density of the lines of force in the bar with its extension. The curve obtained is similar in character to the saturation curve of iron, the extension of the bar approaching a limit as the induction density is increased. In this respect it entirely differs from the curves obtained by Mr. SHELFORD BIDWELL, who, in the course of an exhaustive research on this subject, showed that the extension of the iron attained a maximum value, and that further increase of the magnetising force caused the bar to shorten. He even showed that strong magnetic forces caused the iron to contract by about one-part in 150,000. The apparent inconsistency of these results and of those of M. BERGET does not in any way detract from the interest of his method. The apparatus seems suitable for lecture demonstrations, and is compact and portable.

MR. OLIVER HEAVISIDE commences in our present issue the fourth chapter of his present work, and leaving for the moment the rather difficult analytical treatment of the electromagnetic theory, he introduces the discussion of plane waves by at least two columns of most interesting plain prose. It may seem invidious thus to call attention to a particular article, but we do so because it is safe to assume that a considerable number of our readers occasionally pass over Mr. HEAVISIDE'S contributions, hastily assuming that they are always of a profoundly mathematical character.

Paris.—The central lighting station for the Champs Elysées district is about to come into operation.

Post Office Appointment.—Mr. H. J. Vase, Technical Officer, has been appointed Superintending Engineer, vice Mr. J. Gavey.

Canterbury.—It is announced that the Brush Company have accepted the terms upon which the Town Council are disposed to make over their Provisional Order.

Yarmouth.—The ratepayers of Yarmouth have met together and voted by an overwhelming majority that the Town Council do not proceed further with the proposed electric lighting scheme.

The Hazeltine Coated Carbon.—According to the *Electrical Engineer* of New York, Mr. C. W. Hazeltine, of St. Louis, Mo., has recently discovered that by coating carbons with copper, of about the same thickness as that usually employed, and then with a heavier coating of zinc, the carbons can be made to burn nearly twice as long as with merely the copper covering.

The Dissipation of a Static Charge.—In a recent number of *Wiedemann's Annalen* are described some experiments by Narr on the rate of dissipation of a hollow charged sphere at temperatures varying from 0°C. to 100°C. The rate of loss of charge was practically unaffected, only a 1-10th increase being noted, in spite of the convection currents set up by the heated sphere.

Nelson.—On Friday evening last the municipal central lighting station was inaugurated. Some 450 lights are already connected up. The generating station is at the Corporation Gasworks, and the steam pressure of 80lb. required for driving the engine is supplied by waste heat from the retort-house. The plant is capable of supplying 600 16-c.p. lamps. Insulated cables laid in iron pipes are used.

Australian Land Lines.—The Governments of Queensland and Western Australia are in communication with reference to a proposal to connect the telegraph system of Northern Queensland with Western Australia, so as to make communication

Hosted by Google

complete round the Australian coast in case of an attack by a hostile fleet. The Queensland Government has agreed to carry the Queensland lines as far as Port Darwin.

Interurban Telephony.—The business men of Minneapolis and St. Paul will not rest easy now, says the *Western Electrician*, until they have telephonic communication with Chicago. It is estimated that the line will cost £12,000, and that an annual income of £3,000, or about £10 per day, will be required to cover interest, depreciation, working expenses, &c. The distance in a bee-line is about 350 miles.

Senegal-Pernambuco	December 27, 1892

* Communication with South Africa is still maintained by the East Coast route.

The French Government and the Telephones.—Anyone wishing to obtain reliable statistics with regard to the result of the Government purchase of the telephone system of France cannot do better than digest the report on the subject published by the Directeur Général des Postes et Télégraphes. It is to be found in the July-August number of the *Annales Télégraphiques*, of which it takes up some 56 pages.

The Proposed Trans-African Land Line.—The following letter, signed L. Hirsch and Co., referring to the African Trans-continental Telegraph scheme, appeared in Friday's *Times* :—

Sir,—It having been brought to the notice of the Hon. C. J. Rhodes that a rumour has been circulated by the Havas Agency to the effect that the African Trans-continental Telegraph scheme has been abandoned, Mr. Rhodes requests us to-day, by telegraph from Marseilles, to emphatically deny this statement, and to affirm that operations are to be immediately commenced. Instructions have been already given for the requisite legal steps to be taken for incorporating the Company, and as soon as this is done subscribers will receive the letters of allotment.

Railway Telephones.—In connection with the recently threatened strike of the telegraph operators on the Jersey Central Railroad, it was, says the *Western Electrician*, announced that the Company had taken steps to protect itself, and, anticipating a "walk out," had placed long distance telephones in its stations by means of which, it was hoped, the business could be continued without the operators. Whether there was any foundation for this report cannot be stated positively, but certain it is that the differences between the men and the Company were soon settled, and there is reason to believe that the men did not secure the advance in their wages that was the principal point in dispute.

Hanley.—An inquiry was held at Hanley on Thursday last week by an inspector of the Local Government Board with regard to a proposal of the Town Council to adopt a system of electric lighting throughout the borough. The Town Clerk stated that on September 16th the Council accepted the tender of the Brush Company for £15,780, which included the whole plant, engines, and mains. Buildings would cost £8,000. Several large ratepayers supported the application of the Council, while the ex-Mayor and others opposed the scheme on the ground that the town was already overburdened with rates. It was also pointed out that trade throughout the district had never been in such a bad state.

The Lighting of Trolley Lines.—In a letter to the *Electrical Engineer* of New York, X. I. M. inquires why the electric tramway companies continue to illuminate their tracks at night by the arc between a defective trolley wheel and the wire. He has, he states, noticed at times melted metal drop from the trolley to the top of the car and the ground below. "If trolley poles were properly attended to when out of adjustment, and if eccentric or defective trolley wheels were removed when necessary and trued up or new ones substituted, it would make the poor, overworked motor beneath the car put on the seraphic smile supposed to be worn only by angels when having their photographs taken for a Sunday-school picture."

The Prizes of the Académie des Sciences.—On December 19th the Académie des Sciences held its annual general meeting. The Poncelet prize was awarded to Sir John Fowler and Sir Benjamin Baker; the Montyon prize was obtained by M. Raffard for his well-known elastic coupling and brake; the Gay prize was given to M. Moureaux for his magnetic survey of France. Amongst the prizes offered are the Vaillant (4,000fr., 1894) for "An investigation of the chemical and physical causes which determine the existence of the rotatory power of transparent bodies, especially from an experimental point of view." The Gaston Planté prize of 3,000fr., to be given to any Frenchman making an important electrical discovery or invention, will be awarded for the first time next year (1893).

Electric Traction and the Telephone.—The Port Defiance, Tacoma, and Edison Railway, says the *Scientific American*, has in operation an appliance designed to prevent delays when an accident happens to any of the cars along the line. The appliance is an ingenious telephone arrangement, so connected with the main office that the conductor can telephone what the trouble is and all the details, so that arrangements can be made at the office to avoid delay of other cars on the line. Along the line between Point Defiance and Edison a telephone wire is strung, and there are special poles, down which proper wires run to an average man's height from the ground. Each car carries a telephone instrument, which can be connected with the wires and communication with the main office obtained. After notice of a breakdown is received the remaining cars on either side of the break can be operated by office orders through the telephone, and thus kept running to time.

Copenhagen.—The central station at Copenhagen, which is a municipal concern, has, says our Scandinavian correspondent, found it expedient to bring about a 25 per cent. reduction in the price of electricity for lighting. The price now is 6 öre or four-fifths of a penny per 100 watt per hour ; *i.e.*, 8d. per Board of Trade Unit. From a financial point of view, there does not appear to be any great objection ; for instead of, as calculated, having an average load of 16,000 lamps all the year round, it is likely to be 17,000 lamps, and their average time of burning will probably be 500 and not 400 hours, which will raise the consumption from 352,000 kilowatt hours to 467,000 kilowatt hours. This consumption should, then, at the reduced rate, bring in almost exactly the same revenue as before. There will, of a necessity, be an increased expenditure for fuel and wages, and it is reckoned that the annual addition to the renewal and extension fund will have to be reduced.

Zürich.—The municipal central station at Zürich has recently come into operation. At first it was intended to have continuous-current for the arc lights, and alternate-current for the glow lamps, and to employ water-power (the falls of the Limmat) exclusively. The laying down of two separate sets of mains and generating plant was, however, found to be too expensive, and as the falls of the Limmat supplied a very variable amount of energy, it was finally decided to use auxiliary steam-power and to employ the alternate-current throughout. The central station is situated near the Town Waterworks. The plant comprises two 175-H.P. low-pressure turbines; one 300-H.P. compound steam engine ; two 30-H.P high-pressure turbines. Distribution is carried out on the transformer sub-station three-wire system. There are at present nine sub-stations. Some 3,200 16-c.p. lamps are connected to the mains, and 75 arc lights. The municipality imposes a fixed charge of 10fr. per annum per lamp installed, and charges at the rate of 6¼d. per Board of Trade unit for energy actually supplied.

The Thomson-Houston Electric Light Carbon Factory.—If the attitude towards electrical manufacturers disclosed in the following paragragh which appeared in *Electricity* of New York, on November 23rd, were usual in this country, fires would, perhaps, be more frequent and dividends less rare. The Thomson-Houston Carbon Company's factory at Fremont, Ohio, destroyed by fire in February last, is being rebuilt, the citizens having collected some $35,000 and given it to the Company as a bonus to keep the factory in Fremont, as it was understood the Directors were in favour of building elsewhere. The new plant will be much larger than that destroyed. The building will be 336ft. by 70, and will be of brick and iron, with a slate roof. The engine and boilers for the main factory have a capa-

Hosted by Google

city of 300 H.P. There will also be a machine shop, the power for which will be supplied by a 150 H.P. engine. The retorts for the carbons are already finished, and work is being rapidly pushed on the baking ovens. It is expected that the factory will be in full operation by the beginning of the new year, when a force of from 300 to 400 hands will be employed, and the output of carbons will be about 3,000,000 a month.

Exports of Telegraphic Apparatus.—The statistics of our exports of telegraphic wires and apparatus connected therewith, as shown in the November Board of Trade returns, accentuate the very disappointing comparison shown in previous returns. The value of our exports in November was less than in the previous November, and very much less than in the November of 1890; and the total exports of the eleven months compare very unfavourably indeed with corresponding figures of the first eleven months of either last year or the year 1890. Below we give a statement of the exports for the first three quarters, and for the first two months of the last quarter of the present year, in comparison with the corresponding figures of 1891 and 1890 :—

	1890.	1891.	1892.
First Quarter	£324,670 ..	£653,081 ...	£96,079
Second Quarter	397,042 ...	331,449 ...	579,756
Third Quarter	210,280 ...	342,106 ...	124,605
Nine Months	931,992 ...	1,326,636 ...	800,440
October	335,064 ...	38,167 ...	31,198
November	246,378 ...	25,143 ...	39,993
Total Eleven M'ths...	£1,513,434 ...	£1,389,946 ...	£871,631

The Speed of American Electric Cars.—The St. Paul Council, says the *Western Electrician*, has passed an ordinance regulating the speed of electric cars. It prescribes limits for the centre of town, and directs that within these boundaries eight miles an hour shall not be exceeded. In the outside districts the cars may be run twelve miles an hour. The agitation of this matter has called attention to the statistics of street railway accidents. The St. Paul police reports show 31 accidents from electric cars during the past six months. The fire department has had frequent collisions with the cars. The speed of cars in other cities is tabulated as follows :—

City.	Centre.	Suburbs.
Cleveland, O.	4	12
Nashville	6	12 to 15
Cincinnati	8	—
St. Louis	8½	10
Louisville	9	12
Syracuse, N.Y.	6	—
Memphis	15	—
Washington, D. C.	9	—
New Orleans	6	—
Baltimore	7	16
Los Angeles	8	—
Sacramento	8	—
Denver	8	12
Portland, Ore.	8	—
Boston	8	12

The average speed allowed in these 15 cities is, it will be seen, 7·9 miles per hour.

The Boston Municipality and the West End Street Railway.—"An interesting controversy between the Boston City Council and the West End Street Railway Company has," says the *Western Electrician*, "been in progress for some time. The Boston aldermen ordered the Company to equip its cars with 'fenders.' The Company replied that it had had the matter under consideration for a long time, but had as yet been unable to decide upon any 'fender' submitted. The Council evidently considered this an evasive answer, and ordered immediate action. The Company thereupon agreed to accept any 'fender' which the Council might recommend. It suggested that a Commission be appointed to examine the 'fenders' submitted for consideration. The Company agreed to pay all expenses and abide by the decision of the Council. This proposition had the effect of silencing the aldermen and convincing the public that the Company was acting in good faith. It is not expected that the Council will accept the Company's proposition, as it is believed the city would be liable for damages should accidents follow the adoption of the 'fender' recommended by the city." Municipalities and companies are much the same all the world over. The former oscillate everywhere between over-sluggishness and drastic ordinances, the latter in all climes retain their characteristic penchant for winning, without in any way deserving it, a name for disinterested philanthropy.

Transmission of Power from the Coalfields.—A Paper was read by Mr. B. H. Thwaite at a recent meeting of the Manchester Association of Engineers, upon a bold scheme for generating power on a large scale by means of gas-engines in the South Yorkshire coal district. The details have been worked out with the assistance of Mr. J. Swinburne. The most interesting part consists of estimates for the plant by Mr. C. E. L. Brown, of Messrs. Brown, Boveri and Co., and by the Maschinen-Fabriken Oerlikon. The figures show that 10,000 H.P. can be delivered and sold in London with 7 per cent. profit for 1·34d. per supply unit. *Industries*, in comparing this scheme with the Niagara supply, says that putting a central station down in an English coalfield means economy, because there is already a market for the power. Putting down power plant to supply power at Niagara at a greater price than it can be produced, say at Pittsburgh, may be successful, but it would be still better to put down a station at Pittsburgh. In England we have better opportunities than in America, as we can put down power stations which can probably produce power more cheaply than it can be provided at Niagara, and, further, we need not wait in this country for towns to grow up to use it. All the English manufacturing towns are within electrical reach of possible coalfield stations. When any scheme like, for instance, the one at Niagara, is to be carried out, it should be carried out quickly. Few people realise the financial effect of loss of time in extensive constructional works. It should be remembered that the capital is often spent in large proportions at the beginning of an undertaking, and if several years lapse before the returns begin to come in compound interest must be allowed during the time of building. The omission of this consideration has brought about ruinous effects in some undertakings, such as docks and railways.

The Proposed Electric Railways.—The Clapham Junction and Paddington Railway Bill proposes the incorporation of a company, the promoters of which include the names of Baron Sudeley, the Hon. E. S. Churchill and Mr. D. F. Carmichael, with power to make a railway four miles one furlong in length, from near St. John's-hill, Wandsworth-road, to the Bishop's-road bridge of the Great Western Railway. The railway is to be constructed in two tunnels by means of compressed air, the tunnels are to be lined with iron or metal plates, and the traffic is to be worked by electricity or other motive power than steam. The capital of the Company is fixed at £1,050,000, in shares of £10 each, with power to borrow on mortgage £350,000. The period for the completion of the works is fixed at five years from the passing of the Act. There are special clauses following in the lines of recent legislation for the conveyance of the working classes over the line at certain times in the morning and evening, at the rate of 1d. per journey. Power is taken in the Bill to pay interest at the rate of 3 per cent. out of capital during construction.—The Edgware-road and Victoria Railway Bill provides for the incorporation of a company, including the names of Sir Frederick Johnstone and others, for the purpose of making a line four miles three furlongs six chains in length, from Edgware-road to Vauxhall-bridge-road at Victoria, with a subsidiary line one furlong four chains in length, from High-road, Kilburn, to Dyne-road. The mode of construction and the manner of working are to be similar to those of other proposed electric railways, and the capital of the Company is set at £1,200,000, in 120,000 shares of £10 each, with power to borrow on mortgage £400,000. The works are to be completed within five years from the passing of the Act, and provision is made for the conveyance of the working classes before seven in the morning or after six in the evening, except on Sundays, Christmas Day, and Good Friday, at fares not exceeding ½d. a mile.—The City and South London Railway Company have also deposited a Bill asking for an extension of time for the construction of the subway authorised by their Act of 1890.

ELECTROMAGNETIC THEORY.—XLI.

BY OLIVER HEAVISIDE.

(*Continued from page 151.*)

§ 176. It has often been observed that the universe is in an unstable condition. Nothing is still. Nor can we keep motion, once produced, to a particular quantity of matter. It is diffused or otherwise transferred to other matter, either immediately or eventually. The same fact is observed in the moral and intellectual worlds as in the material, but this only concerns us so far as to say that it underlies the communication of knowledge to others when the spirit moves, even though the task be of a thankless nature.

The laws by which motions, or phenomena which ultimately depend upon motion, are transferred, naturally form an important subject of study by physicists. There are two extreme main views concerning the process. There is the theory of instantaneous action at a distance between different bodies without an intervening medium; and on the other hand there is the theory of propagation in time through and by means of an intervening medium. In the latter case the distant bodies do not really act upon one another, but only seem to do so. They really act on the medium directly, and between the two are actions between contiguous parts of the medium itself. But in the former case the idea of a medium does not enter at all. We may, however, somewhat modify the view so that action, though seemingly instantaneous and direct, does take place through an intervening medium, the speed of transmission being so great as to be beyond recognition. Thus, the two ideas of direct action, and through a yielding medium, may be somewhat harmonised, by being made extreme cases of one theory. For example, if we know that there *is* a yielding medium and a finite speed, but that in a certain case under examination the influence of the yielding is insensible, then we may practically assume the speed to be infinite. But although this comes to the same thing as action at a distance, we need not go further and do away with the medium altogether.

There is another way of regarding the matter. We may explain propagation in time through a medium by actions at a distance. But this is useless as an explanation, being at best merely the expression of a mathemat cal equivalence.

Now consider the transmission of sound. This consists, physically, of vibratory motions of matter, and is transmitted by waves in the air and in the bodies immersed in it. The speed through air is quite small, so small that it could not even escape the notice of the ancients, who were, on the whole, decidedly unscientific in their mental attitude towards natural phenomena. Suppose, however, that the speed of transmission of sound through air was a large multiple of what it is, so that the idea of a finite speed, or of speed at all, did not present itself. We should then have the main facts before us, that material bodies could vibrate according to certain laws, and that they could, moreover, set distant bodies vibrating. This would be the induction of vibrations, and it might be explained, in the absence of better knowledge, by means of action at a distance of matter upon matter, ultimately resolvable into some form of the inverse square law, not because there is anything essentially acoustical about it, but because of the properties of space. Furthermore, we should naturally be always associating sound with the bodies bounded by the air, but never with the air itself, which would not come into the theory. A deep-minded philosopher, who should explain matters in terms of an intervening medium, might not find his views be readily accepted, even though he pointed out independent evidence for the existence of his medium—physiological and mechanical—and that there was a harmony of essential properties entailed. Nothing short of actual proof of the finite speed of sound would convince the prejudiced.

Now, although there is undoubtedly great difference in detail between the transmission of sound and of electrical disturbances, yet there is sufficient resemblance broadly to make the above suppositional case analogous to what has actually happened in the science of electromagnetism. There were conductors and non-conductors, or insulators, and since the finite speed of propagation in the non-conducting space outside conductors was unknown, attention was almost entirely concentrated upon the conductors and a suppositional fluid which was supposed to reside upon or in them, and to move about upon or through them. And the influence on distant conductors was attributed to instantaneous action at a distance, ignoring an intermediate agency. Again, a very deep-minded philosopher elaborated a theory to explain these actions by the intermediate agency of a yielding medium transmitting at finite speed. But although in doing so he utilised the same medium for whose existence there was already independent evidence, viz., the luminiferous ether, and pointed out the consistency of the essential properties required in the two cases, and that his electromagnetic theory made even a far better theory of light than the old, yet his views did not spread very rapidly. The old views persisted in spite of the intrinsic probability of the new, and in spite of the large amount of evidence in support of the view that some medium outside conductors, and it may be also inside them as well, but not particularly conducting matter itself, was essentially concerned in the electrical phenomena. The value and validity of evidence varies according to the state of mind of the judge. To some who had seriously studied Maxwell's theory the evidence in its favour was overwhelming; others did not believe in it a bit. I am, nevertheless, inclined to think that it would have prevailed before very long, even had no direct evidence of the finite velocity been forthcoming. It was simply a question of time. But the experimental proof of the finite speed of transmission was forthcoming, and the very slow influence of theoretical reasoning on conservative minds was enforced by the common-sense appeal to facts. It is now as much a fact that electromagnetic waves are propagated outside conductors as that sound waves are propagated outside vibrating bodies. It is as legitimate a scientific inference that there is a medium to do it in one case as in the other, and there is independent evidence in favour of both media, air for sound and ether for electrical disturbances. It is also so excessively probable now that light vibrations are themselves nothing more than very rapid electromagnetic vibrations, that I think this view will fully prevail, even if the gap that exists between Hertzian and light vibrations is not filled up experimentally, through want of proper appliances—provided some quite new discovery of an unanticipated character is not made that will disprove the possibility of the assumed identity.

Now, the immediate question here is how to propagate a knowledge of the theory of electromagnetic waves. If we could assume the reader to have had a good mathematical training, that would greatly ease matters. On the other hand, it is hardly any use trying to do it for those who have no mathematical knowledge—least of all for those anti-mathematical attackers of the theory of the wave propagation of electrical disturbances who show plainly that they do not even know intelligibly what a wave means, and what is implied by its existence. But, between the two, I think it is possible to do a good deal in the way of propagation by means of a detailed exposition of the theory of plane waves, especially in dielectrics. By the use of plane waves, the mathematical complexity of waves in general in a great measure disappears, and common algebra may be largely substituted for the analysis which occurs in more advanced cases. Most of the essential properties and ideas may be assimilated by a thinking reader who is not advanced in his mathematics, and what is beyond him he can skip. Besides this, the treatment of plane waves is itself the best preliminary to more general cases.

The problems that present themselves by the artificial limitation to plane waves are often of an abstract nature. There are, however, some important exceptions; the most notable being that of propagation along straight wires, of which the theory is essentially that of plane waves, modified by the resistance of the wires. Before, however, proceeding to the details of plane waves, which will form the subject of this chapter (although it will be needless to altogether exclude connected matters), it will be desirable to prepare the mind by an outline of some general notions concerning electromagnetic waves, irrespective of their precise type.

§ 177. Consider a non-conducting dielectric, to begin with. The two properties it possesses of supporting electric displacement and magnetic induction, which we symbolise by μ and c, the inductivity and permittivity, are, independently of our actual ignorance of their ultimate nature, so related that the speed of propagation v depends upon them in the way expressed by the equation $\mu c v^2 = 1$, or $v = (\mu c)^{-\frac{1}{2}}$. Thus, an increase either of the permittivity, or of the inductivity, lowers the speed of transmission. In transparent bodies we cannot materially alter the inductivity, but we can very considerably increase the permittivity, and so lower the speed. If on the other hand, we wish to have infinite speed, for some practical purpose of calculation, we may get it by assuming either $\mu = 0$ or else $c = 0$. In the latter case, for example, we destroy the power of supporting electric displacement, whilst preserving the magnetic induction. This is what is done in magnetic problems (the theory of coils, self and mutual induction) when we ignore the existence of electric displacement. On the other hand, in the theory of condensers connected up by inductionless resistances, and in the electrostatic theory of a submarine cable, it is the magnetic induction that is ignored, in a manner equivalent to supposing that $\mu = 0$. In either case we have infinite speed or apparent instantaneous action.

Now, consider some of the consequences of the property of propagation with finite speed. Let there be a source of disturbance at a point for simplicity. It may be either an electric source or a magnetic source. By an electric source we mean a cause which will, if it continue steadily acting, result in setting up a state of electric displacement, whilst a magnetic source steadily acting would result in a state of magnetic induction. In the former case there will be no magnetic induction along with the displacement, and in the latter case no displacement along with the induction. Now, if the speed of propagation were infinite in the former case of an electric source, by the non-existence of μ, the steady state would be set up instantly, and consequently all variations of the intensity of the source would be immediately and simultaneously accompanied by the appropriate corresponding distribution of displacement in the dielectric. Similarly, with a magnetic source, if the speed be infinite by the non-existence of c, all variations in the source will be simultaneously accompanied by the distribution of magnetic induction appropriate to the instantaneous strength of the source.

Now do away with the artificial assumption made, and let both μ and c be finite, and v therefore also finite. At the time t after starting a source, the extreme distance reached by the disturbance it produces is vt. That is to say, beyond the sphere of radius vt, whose centre is at the source, there is no disturbance, whilst within it there is. The wave-front is thus a spherical surface of radius vt, increasing uniformly with the time. Along with this continuous expansion of the range of action there are some other things to be considered. The mere spreading causes attenuation, or weakening of intensity as the disturbance travels away from the source. Besides this, the intensity of disturbance is not the same at a given distance in all directions from the source, and since the displacement and induction are vectors, their directions are not everywhere the same. They are distributed in the circuital manner, so that we have expanding rings or sheets of displacement or induction. Whether the source be of the electric or the magnetic kind, it produces both fluxes initially and when varying, and generally speaking to an equal degree as regards energy. This is a main characteristic of pure electromagnetic waves, a coexistence of the electric and magnetic fluxes with equal energies; and if the source be in a state of alternating variation this state of things continues. But if the source, after varying in any way, finally become steady, the generation of electromagnetic disturbances will speedily cease, and the production of a steady state will begin round the source—of displacement if the source be electric, and of induction if the source be magnetic—whilst the previously generated electromagnetic disturbances will pass away to a great distance. In the end, therefore, we have simply the steady state of the flux corresponding to the impressed force, whilst the electromagnetic disturbances are out of reach, still spreading out, however, and in doing so, leaving behind them the outside portion of the residual steady flux due to the source, which steady flux, however, requires an infinite time to become quite fully established.

We may take a specially simple case in illustration of the above general characteristics. Let the source of energy be contained within a small spherical portion of the dielectric, of radius a, and let it be of the simplest type, viz., a uniform distribution of impressed electric force within the sphere. We know by static considerations alone what the nature of the final displacement due to such a source is. It is a circuital distribution, out from the sphere on one half, and in on the other, connection being made through the sphere itself by a uniform distribution; being, in fact, of the same nature as the induction due to a spherical body uniformly magnetised in a medium of the same inductivity as its own. Now, we can describe the setting up of the final steady state due to the source, when it is suddenly started and kept constant later, thus:—At the first moment an electromagnetic wave is generated on the surface of the sphere, which immediately spreads both ways and becomes a spherical shell, whose outer boundary goes outward at speed v, whilst the inner boundary goes inward. At the time $t = a/v$, therefore, the disturbance fills the sphere of radius $2a$, the centre being just reached. The steady state then begins to form, commencing at the centre and expanding outwards thereafter at speed v. At the time $t = 2a/v$, therefore, we have the steady state fully formed within the sphere of radius a, whilst just outside it is an electromagnetic shell of depth $2a$. Up to this moment the impressed force has been continuously working—not, indeed, in all parts of the sphere it occupies, but in all parts passed by the front of the inward wave from the beginning until the centre was reached, and after that, in the parts not occupied by the already formed steady state. Consequently, at the moment $t = 2a/v$, when the steady state is fully formed throughout the region occupied by the impressed force, the latter ceases to work. It has wholly done its work. The amount done is twice the energy of the final complete steady state, say 2U. The rest of the work is done by the electromagnetic wave itself. For the subsequent course of events is that the fully-formed electromagnetic shell of depth $2a$ runs out to infinity, of course expanding on the way, and in doing so it leaves the steady state behind it. That is to say, it drops a part of its contents as it moves on, so that the steady state is always fully formed right up to the rear of the expanding shell during the whole of its passage to infinity. This shell is not a pure electromagnetic wave, with equal electric and magnetic energies. The magnetic energy is constant, of amount $\frac{1}{2}$U, on the whole journey, but the electric energy is in excess. The excess is employed in forming the steady state, so that when the shell has reached a great distance it becomes appreciably a pure electromagnetic wave, having the amount U of energy, half magnetic, half electric, with a slight excess in the latter, to be later left behind in forming the remainder of the steady state. The energy U of the shell is wholly wasted if the dielectric be unbounded, for there is nothing to stop the transference to an infinite distance.

If we wish to form the steady state without this waste of energy, we must bring the impressed force into action very gradually—infinitely slowly, in fact. In this way the energy wasted in the very weak electromagnetic waves generated will tend to become infinitely small, and the work done by the impressed force will tend to the value U, the energy of the steady state.

When the sphere of impressed force is not finite, but is infinitely small, so that it may be regarded as a special kind of point-source, we simplify matters considerably in some respects. For, by the above, the result is that the moment the source starts, say at full strength, the steady state also immediately begins to grow, so that at the time t it occupies the sphere of radius vt. Outside it there is no disturbance, but on its surface is an infinitely thin electromagnetic shell, which performs the same functions as the previous finite shell. That is, it lays down the steady state as it expands, and thus carries out to infinity in itself as much energy as it leaves behind.

Notice, however, this peculiarity, that if we had started with what appears at first sight to be the simpler problem, viz., a point-source, we should be quite unable to see and understand

Hosted by Google

the functions of the electromagnetic shell on the extreme verge of the steady field. The reader may compare this case with that of the establishment of the steady state of displacement due to another kind of point-source, viz., electrification suddenly brought to rest at a point after previous motion at the speed of light, as discussed in § 55. There is a perfect similarity as respects the uniform growth of the steady state. But the nature of the bounding electromagnetic shell is not the same. In the case of electrification it belongs to the zero degree of spherical harmonics; in our present problem it is of the first degree.

If, after keeping on the impressed force at a point for, say, an interval τ, we suddenly remove it, this is equivalent to keeping it on, but with the addition of an impressed force which is the negative of the former. From this we see that the result of putting on the impressed force for an interval τ only is to generate a shell of depth $v\tau$, which runs out to infinity. Within this shell is the steady electric displacement due to the source appropriate to the instantaneous position of the shell. On its outer surface is an electromagnetic wave moving out to infinity, and generating or laying down the steady electric displacement as it goes, whilst on the inner surface is another wave running after the first, and undoing its effects. That is, it takes up the displacement laid down by the first wave, so that inside the inner wave (just as outside the outer) there is no disturbance.

(To be continued.)

ERRORS OF OBSERVATION IN THE THREE-VOLTMETER METHOD.

BY A. RUSSELL.

With the usual arrangement, let V, V_1, V_2, W and A be the true values of the volts, the watts and the amperes in the circuit. Then, whatever the law of the applied E.M.F.,

$$2\,V_2\frac{W}{A} = V^2 - V_1^2 - V_2^2 \quad \ldots \quad (1)$$

where V_1 is the potential difference at the ends of the inductive resistance. We shall discuss the error introduced into the calculated value of W by errors of observation in reading the voltmeters. The error introduced into W by the ammeter reading is obviously proportional to the error in the ammeter reading.

Let the observed readings of the voltmeters be $V + x\,V$, $V_1 + y\,V_1$, $V_2 + z\,V_2$, where x, y, and z may have any values between $\pm a$, $\pm b$, $\pm c$ respectively. Let W′ be the calculated value of the watts; then,

$$2\,(V_2 + zV_2)\frac{W'}{A} = V^2(1+x)^2 - V_1^2(1+y)^2 - V_2^2(1+z)^2 \quad (2)$$

$$= 2\,V_2\frac{W}{A} + (2x + x^2)\left(V_1^2 + V_2^2 + 2\,V_2\frac{W}{A}\right) - (2y + y^2)\,V_1^2 - (2z + z^2)\,V_2^2$$

$\therefore$ From (1)

$$(1+z)\frac{W'}{W} = 1 + 2x + x^2 + \frac{A}{2\,V_2\,W}\{V_1^2(2x - 2y + x^2 - y^2) + V_2^2(2x - 2z + x^2 - z^2)\};$$

$$\therefore \frac{W'}{W} = 1 + 2x - z + x^2 + z^2 + \frac{A}{2\,V_2\,W}\{V_1^2(2x - 2y + x^2 - y^2) + V_2^2(2x - 2z + x^2 + z^2)\} + \text{terms multiplied by } x\,y,\ x\,z,\ \&c. \quad \ldots \quad (3)$$

$$= 1 + 2x - z + \frac{A}{V_2\,W}\{V_1^2(x - y) + V_2^2(x - z)\} \quad \ldots \quad (4);$$

neglecting terms multiplied by small quantities of the second order. Now, in the measurement, V_1 and A are fixed, and we have to find the value of V_2, which makes $\frac{W' - W}{W}$ a minimum. This value in any particular observation depends upon the values of x, y and z, and can be found from (4). The most important error to consider, however, is the maximum possible error arising from errors of observation. This error is got by putting $x = a$, $y = -b$, and $z = -c$.

Then $$\frac{W' - W}{W} = 2a + c + \frac{A}{V_2\,W}\{V_1^2(a+b) + V_2^2(a+c)\}$$

$$= 2a + c + \frac{A}{V_2 W}(V_1\sqrt{a+b} - V_2\sqrt{a+c})^2 + \frac{2\,A\,V_1}{W}\sqrt{(a+b)(a+c)}.$$

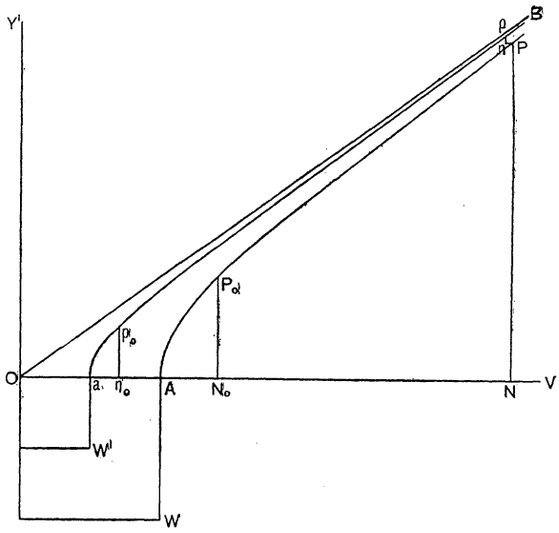

FIG. 1. Effect of Small Errors Pn and pn in determining the Value of the Area of O W.

The value of V_2 that makes this expression least is obviously

$$V_1\sqrt{\frac{a+b}{a+c}} \quad \ldots \quad (5).$$

In this case $$\frac{W' - W}{W} = 2a + c + 2\frac{A\,V_1}{W}\sqrt{(a+b)(a+c)} \quad \ldots \quad (6).$$

For example, suppose we are measuring the power consumed in a circuit in which $\frac{W}{AV_1}$—the power factor—is small, equal to 0·1 (say), and that we are using three exactly similar voltmeters which we can read to ± 0·1 per cent. Then the maximum error in W is 4·3 per cent., when V_2 is equal to V_1. If

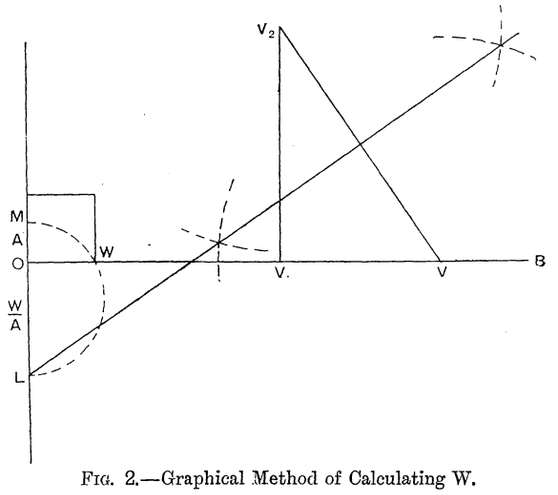

FIG. 2.—Graphical Method of Calculating W.

the voltmeters are not exactly similar instruments, a, b and c will not be all equal, and we see from (5) and (6) that the best arrangement is to use the most accurate voltmeter to measure V and the least accurate to measure V_1, and to make V_2 greater than V_1.

Again, from equation (3) we at once deduce that the mean value of W′/W

$$= 1 + \tfrac{1}{3}(a^2 + c^2) + \frac{A}{6V_2W}\{V_1^2(a^2 - b^2) + V_2^2(a^2 + c^2)\}$$

Hosted by Google

As this mean is deduced from a very large number of observations, and as we only take a few observations in practice, it is better to give V_2 a value that makes the maximum possible error least than to give it the value that would make the error in the mean of a very large number of observations least. Hence, (5) and (6) can be taken as working formulæ.

It is instructive to consider the problem graphically. Let $V_2 = V_1 = V'$; then the fundamental formula may be written

$$V^2 - 2V'^2 = 2rW,$$

where r is the non-inductive resistance.

Suppose we regard V and V′ as variable and r W as constant, and plot out the points P which satisfy this relation; we get the curve A P_0 P (Fig. 1). This curve is the curve got by cutting a cone which has O V for its axis and O B for a generating line, by a plane parallel to its axis. In the figure $OA^2 = 2rW$ and the angle B O V is a little greater than 35deg. Now, from the arrangement of the voltmeters the least value of V′ is $\frac{1}{2}$ V; therefore, all the points lie further up the curve than P_0, where ON_0 is equal to 1·414.O A. We may imagine a large number of these curves to be drawn, each corresponding to a different value of W. In the figure we have drawn two such curves—one corresponding to W, the other to $\frac{1}{4}$ W. We see that the further P is up the curve, the more likelihood is there that small errors in the value of V and V′ will displace P on to the wrong curve. We deduce, as before, that V'^2/rW, or AV_2/W, should be as small as possible in order that the method may give accurate results.

The following graphical method of calculating W illustrates the difficulty of finding W correctly by the formula. Let O B and O L (Fig. 2) be two lines at right angles to one another. Measure off O V = V, O $V_1 = V_1$. From V_1 draw $V_1 V_2$ perpendicular to O B and equal to V_2. Join V_2 V, and bisect it at right angles by a line meeting O L in L. Then O L is equal to W/A. To get W, produce L O to M, making O M equal to A. On L M as diameter describe a semicircle, cutting O B in W. Then the square on O W measures the required watts. We see by this construction how errors in the measurement of V, V_1, or V_2, depress or elevate L, and thus increase or diminish the true value of the watts.

AN AMERICAN DIRECT-DRIVEN DYNAMO.

While the practice of coupling dynamos direct to high-speed engines is firmly established in this country and the rest of Europe, belt and rope driving are still popular in America. In this country rope driving appears to be adopted for the most part because the makers of the engines are unwilling or unable to run at sufficiently high speeds; in Germany, however, this difficulty is overcome simply by increasing the size of the dynamos. For ship-lighting purposes direct driving is now admitted to be imperative, even if only from considerations of space.

The General Electric Company of New York (under which title our readers will remember the Edison and Thomson-Houston interests have been amalgamated) have sent us particulars of generating plant which has been fitted on a steam-ship of the whaleback type, the "Pillsbury," (Fig. 2). A small room (Fig. 1), 8ft. square, was all that could be spared. This precluded the employment of a belt-connected plant, and a generating set of the Thomson-Houston International Company type was therefore adopted. The dynamo is of 150 lights capacity, and is directly coupled to a 15 H.P. engine, both having a

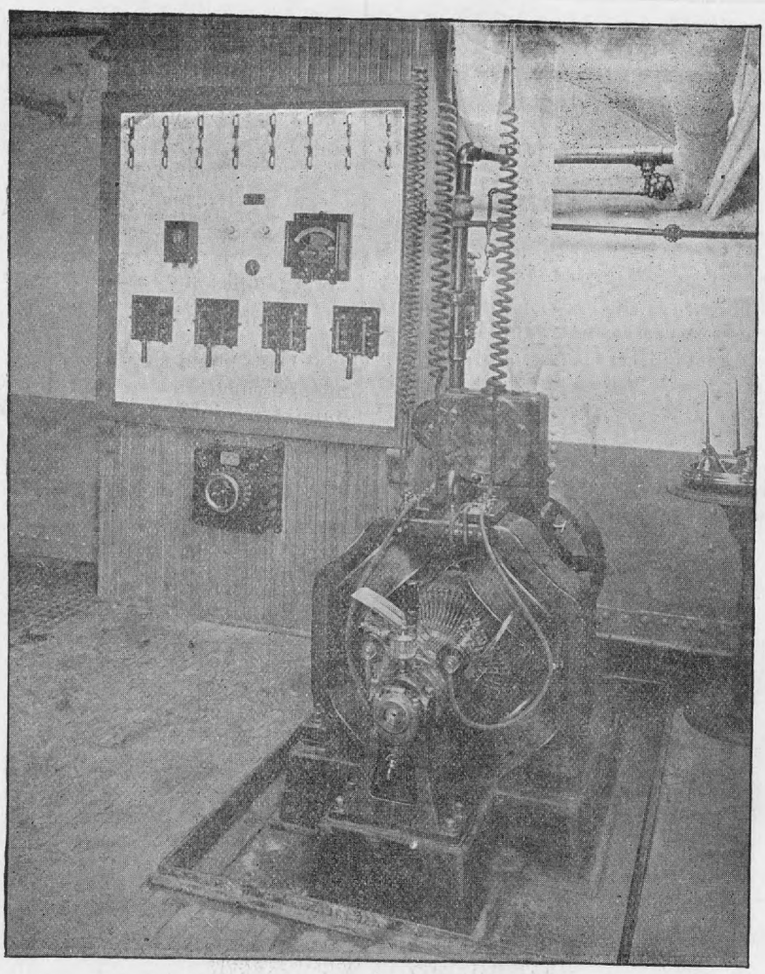

Fig. 1.—Thomson-Houston International Company's Direct-Driven Plant.

Hosted by Google

common bed plate. We are informed that under careful tests the engines showed a very high economy. The generator is of the 4-pole type, compound wound, having an automatic regulation within 2 per cent. over the entire range from no load to full load. The commutators are cross connected, so that only two brushes, 90deg. apart, are used. The rheostat is of the iron frame type. The engine and dynamo are both provided with self-oiling bearings. Behind the engine, and attached to the wall, is a white marble switchboard. The dynamo room is in the after portion of the vessel, on the first lower deck. The vessel is wired in the usual manner for 150 lights. The plant on the sister whaleback, the "Washburn," is of a similar character.

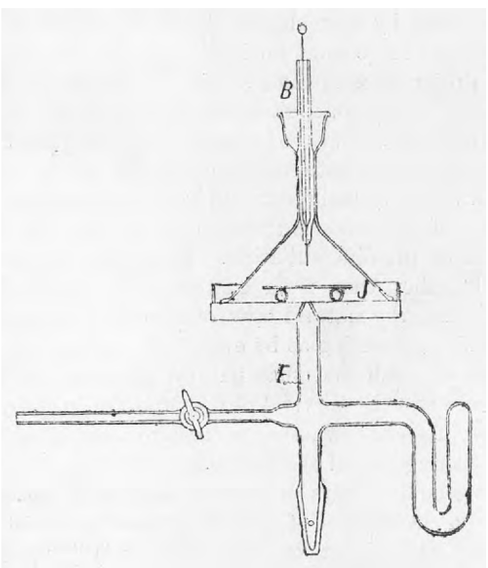
ON THE METALLIC LAYERS OBTAINED BY DISINTEGRATION OF CATHODES.*

BY J. MOOSER.

The form of Geissler tube employed by the author is shown in the accompanying figure. B is the cathode, F is the anode. Between them, resting on glass tubes, is a plate of glass J, upon which the deposit takes place. It is permissible to assume that the metallic particles torn from the cathode follow the direction of the lines of force. If, therefore, B terminates in a small ball, and J is not too far off, it may be assumed that the trajectories of the metallic particles are rectilinear and equally divided in the space round the centre of the ball. It is thus easy to calculate the relative thickness of metal deposited on J when at different distances from the centre of B. To arrive at the relative thicknesses of metal the author compared the resistance of concentric rings of the metallic deposit which he obtained by laying the metallised surface of the plate J on a board provided with concentric grooves containing mercury.



Assuming that the deposited platinum had a density of 21, the author was able from the absolute resistance of a ring, and the weight of J, to deduce the absolute thickness and specific resistance of the deposit. The lowest figure obtained for the specic resistance of platinum deposited in hydrogen was 18 times that of pure platinum. When the deposit takes place in air its specific resistance may amount to 82 times that of platinum.

EVOLUTION IN ELECTRICAL ENGINEERING.

Electrical engineering, the offspring of electrical science and of the engineering profession, has now attained the age of about sixteen years, and having acquired something more than a rudimentary education and training, the time has arrived when some beginnings of specialisation may be looked for. There is much to be said in favour of the view that a lad should not be encouraged, or, at all events, compelled, at too early an age, to choose a trade or profession. It appears that while in a less developed state of society competition was milder, and there was less hurry for a youth to begin the battle of life, yet selection of a vocation was more easy, and willing selection was made by mere boys. Many a young man to-day has to be forced into some business, caring little, and as likely as not a wrong start is made. We are reluctant, therefore, to urge that electrical engineering, which is now arriving at years of discretion, should be forced into any specialisation; it is jostled hotly enough between rash adventurers, greedy speculators and visionary theorists; and we will only glance at a few indications of separation into different branches, and consider the result of the differentiation. Borrowing this term from biological rather than from mathematical science, we are reminded that the natural laws of evolution must be obeyed by electrical engineering as by every other process of development, and we shall find that natural selection, the struggle for existence and the survival of the fittest must result in the production of species, whether we turn to the animal kingdom or to a dealer's stock of electric light switches.

In the good old days of one of the parents of electrical engineering, electricians of all kinds were physicists. The first commercial outlet for the commercially minded was telegraphy, and long after came the Gramme dynamo, the Jablochkoff lamp and the infancy of electric lighting, and theory began to diverge from practice, science from business; so, also every mechanical engineer was at one

Hosted by Google

time a millwright, probably with nothing less than quarter-inches on his rule; nor was even this wanted when he designed an engine with the toe of his boot on the dusty floor of the pattern shop, filling in the details with a lump of chalk. We dare wager that a large number of electrical engineers have never had a lump of chalk in their pockets since they adopted the profession which they have honoured by their choice.

But a few years ago an electrical engineer was ready to turn his attention to any job short of making a submarine cable or an electropathic belt. The first sign of differentiation was the appearance of the man who had a capital arc lighter and who was too busy to build any other kind of dynamo, and of the chemist who made glow lamps. But most of those who threw their energies and capital into the business plunged after every job that presented itself. True, they often failed to make a profit, but what they did earn was in cash, and not in "ordinary shares." The enterprising gasfitter then began to turn his brackets and fittings upside down, and so a new branch of trade was created. Was it trade, by-the-bye, or profession? No matter, it paid pretty well. Another indication that evolution is doing its work is the existence, and the increasing number, of firms who undertake wiring, and who neither sell nor manufacture supplies and sundries; of dynamo makers who eschew the taking up of carpets and floors, and ruining pretty rooms with ugly switches, and uglier lampholders and shades; of cable makers who do not stock the wood casing so dear to insurance inspectors, and of dealers in everything who will undertake no responsibility after goods have crossed their counters. To these we might add managers of financial departments who repudiate responsibility for the industrial branches of their establishments, and a score of other specialists. And behind all, and yet ahead of all, is the man of science. The appearance and the development of distinct species is a clear sign of progress. We altogether combat the idea that any ironmonger can wire a house, and we consider that it is most reprehensible to encourage him to try his hand at it. But wiring, though it needs special knowledge, is a far less complex trade than that of plumbing, needing none of the dexterity necessary for wiping a joint, nor acquaintance with sanitary science or highly complicated hydraulic problems. Wiring is, no doubt, destined to take its place as a trade with gasfitting; but like gasfitting, may be taken up as a branch by important firms.

It would be well if in this process of evolution little more differentiation arose between the electrician and the electrical engineer, and between the man of science and the man of business. The hopeful products of our technical colleges, brimful of knowledge which has been denied to their seniors, cause much of the confusion which at present exists. The recent presidential address by Mr. Atkinson, the article in our columns last week by Mr. Cunynghame, and the leading article in the *Engineer*, which we reproduce in another column, treat of the shortcomings of technical education. If scientific men destined to remain, and content to be, scientific men need this training—and Prof. Schuster's address at Edinburgh last summer raises thereon more than a doubt—these young hopefuls may, if they can afford it, go straightway and be scientific men, and given the run of a workshop they may design and build magnificent dynamos; but if these do not pay, they are brilliant scientific experiments, not engineering. Engineering is a business, and the success of a business is very properly measured by its cash profits. Success in science is not so measured, or Galileo and Faraday would, indeed, have been sad failures. Science has, and science will ever continue to have, attractions that cannot be measured in money. But even in the business of engineering occasions arise, as was the case in the supply of dynamos to the Admiralty under its stringent specifications, where real skill is called for, and where it is not only worth while but necessary to design each size from the beginning; the result being to raise the whole level of design. That there was but little profit to the contractors in this particular venture is now of small importance. A little more distinction between science and business would lead to a better understanding of those results which are now called failures. To design a new dynamo for each new order is a temptation to every enterprising manufacturer, and to turn out a machine of high efficiency is the aim of many an ambitious engineer. To add a few inches to the length of a stock size of armature and to widen the field magnet may be unscientific; any fool can do it, but it pays. Niceties of design may have to be sacrificed in order to bring machines into a properly standardised set, but it is those who make the sacrifice who will succeed—as success is measured. It is fortunate that electrical engineering is throwing out so many branches, for specialisation will thus become compulsory, and the concentration of the energies of able minds on distinct departments will be better both for the development of the industry and the individuals of whom it is composed.

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Continued from page 212.*)

Our attention may now be directed to some certain points. We have spoken of disruptive sparks and arcs, of current, and electromotive force, or potential. Some effects in particular however, may be noted. When dealing with the formation of the arc, we mentioned the great heat as being due to the current. A high voltage with or without much current, produces on communication what is called a "shock," best made analogous perhaps to a vibration more or less terrific, according to its strength. But the current burns. A large current at a very low voltage will produce scarcely any "shock," but may produce great heat. This latter, however, depends on there being a resistance to its flow. A resistance being offered, the work done in overcoming it is the immediate source of the heat that will be manifested. If there be little or no resistance, there will likewise be little or no heat. Now there is always *some* heat with every kind of spark; but the point we wish to arrive at may be made more clear perhaps thus. Suppose an animal is to be killed by electricity. It may be put in a circuit with a high voltage and small current, say 20 amperes at 2,000 volts. On switching on the current, it is struck dead instantly by the "shock" due to the high potential; while the body subsequently will show no signs of burning, for it will not have offered sufficient resistance for the small current to take effect. On the other hand, if intense heat be desired to burn or melt any otherwise refractory substance, large currents are required. Thus we find in the case of electric smelting furnaces wherein the intensest heat is obtained by means of the arc, that extremely large currents of even 12,000 or 14,000 amperes are used: while there may be only an electromotive force of 30 to 60 volts. It should be noted here moreover, that the resistance that gives rise to the heat is not that due to the substance being acted upon, but to the arc itself; hence the comparative lowness of the electromotive force. Thus we observe that for great heat extremely large currents are supplied, at not necessarily a high potential; and so it is to the presence of *current* that heat is due in an arc, with all its concomitant effects, such as burning, melting, and volatilisation.

Now we have already dwelt on the destruction of the electrodes of an arc. This, however, is not the only source of expenditure in either material or energy. For it is supposed

Hosted by Google

that a back electromotive force is set up in the arc, which impedes the flow of the normal main current. Hence, besides the energy necessary to overcome the resistance of the gas which is the product of the volatilisation of the carbon, energy is also spent in overpowering this back electromotive force. A complete theory of the arc would however appear to be wanting. But at the British Association meetings in Edinburgh this last summer, a Paper on the subject was read by Prof. Silvanus P. Thompson (see *The Electrician* for August 26th, p. 460), should any feel interested in knowing more. Further however, when considering the arc and its generation, we have observed that it is commenced by a disruptive spark, which may be of either our third or fifth orders, accompanied by great heat, due principally as we now find to the presence of the current: for a statical electric spark wherewith there is practically no current, does not cause much heat. A further point however to be noted, is the extremely small amount of time occupied by a disruptive spark. This is in fact infinitesimal; the time taken by so great a disruptive spark as a flash of lightning being at the most, only about the hundred thousandth part of a second.

We have now reached that stage in our progress, however, when we may bring the above to a practical bearing. Thus we may consider what happens on the opening of an electric switch such as is in common use. When this is done, usually a flash is seen. Moreover, the switch may so be held that an arc is maintained between the moving tongue or contact piece and the fixed contact piece. But allowing it to be opened quickly, even by the means of some spring snap arrangement, the opening will still take a very appreciable amount of time compared to the extremely small period required for the spark. No switch could endure, whereof the moving parts moved with a speed even approaching that of a flying bullet.

The upshot hence in the case of a flash seen at the opening of a switch, is that whereas this may have for its commencement a self-induction disruptive spark of our third (or fifth) order, the remainder of the flash will be a momentary arc.

Now we found when examining the arc between two carbons, that the precursory spark volatilised some particles of carbon; that is, heated them so intensely as to turn them to gas. Further, we noted that on the establishment of the arc both carbons were burnt, owing to their oxidisation in the air; but the positive carbon at twice the rate of the negative. Now, metals will volatilise more easily than carbon; and moreover, they also oxidise when heated and exposed to the air, even when not fused. Hence in the case of the flash seen with the switch, and drawing our inference from the arc between two carbons, we find that both contacts are exposed to destruction. Firstly, some of the metal will be volatilised by the precursory spark; and secondly, the positive contact will be burnt and oxidised away at twice the speed of the negative by the following momentary voltaic arc. This however assumes an ordinary current, such as may be large enough to maintain an arc, and an ordinary electromotive force of but a few hundred volts at the outside. In the case of very high voltages, and a current too low practically for an arc, the flash on the opening of a switch would be a momentarily continuous disruptive discharge of our fifth order. Both contacts may consume away somewhat, owing partly to their oxidation on being heated and partly by volatilisation. But returning to the case of a switch in a circuit where there is an appreciable current, we find this peculiarity, that, inasmuch as in point of the time taken by the flash by far the larger proportion is occupied by the arc, it is the arc that works the greater destruction, chiefly to the positive electrode.

Having thus far entered into the subject generally, we may now perhaps consider ourselves the better prepared to examine with some closeness what is our main subject, the sparking that takes place at the brushes on a commutator.

(To be continued.)

Public Use of Mexican Railway Telegraphs.—The Mexican Railway has posted a notice in its telegraph offices prohibiting the use of the Mexican Railway telegraph lines so far as the public is concerned.

THE ELECTRIC RAILWAYS OF THE UNITED STATES.

We reproduce from *Electricity and Railroading*, of Boston, the following list of electric railways actually in operation in the United States at the present moment, and about which particulars are forthcoming. It is a portentous catalogue, and one which may well excite envy in a land where jobs are few and electrical engineers are many. Electric traction, especially where the overhead trolley system is in force, may not be an unmixed blessing—what is?—but there can be no two opinions as to its superiority over every other mode of traction for ninety-nine tramways out of every hundred. We shall publish next week, as is our usual custom, a similar table for the United Kingdom. It is as well that we do not place the two lists side by side; the contrast, be the cause of it what it may, would be painful to our national *amour propre*. It will be seen that, according to this compilation, the electric railway mileage of the United States totals up to over 2,500, with nearly 4,000 motor cars.

We may add that we have considerably compressed this table, since a large proportion of the particulars given by our Boston contemporary are of local interest only. From these totals it will be seen that in the United States three motor cars to every two miles of track is a fair average allowance. In country places, of course, the proportion is more nearly one to one, whilst in busy cities, such as Pittsburgh, it is more like two to one. Another relation, which appears to obtain under widely different circumstances, is that it is necessary to lay down about 20-H.P. of electric plant at the central station for every motor car running on the line. In a Paper read more than two years ago before the American Institute of Electrical Engineers (see *The Electrician*, Vol. XXIV., page 213), Mr. O. T. Crosby evolved another useful relation, namely, that for every car mile run on the line about 1 H.P.H. is expended at the power house. Among the lines contained in the list below, nearly 200 in number, it is worth noticing that only one (Milford) is on the storage-battery system, and only five obtain power from water-falls.

LOCATION. State and Town.	ROAD EQUIPMENT. m=miles, st=standard, g=gauge, gr=girder rail, Tr=T-rail, mc=motor cars, c-br=centre-bearing rail, s-br=side-bearing rail.	STATION EQUIPMENT. T-H=Thomson-Houston, gen=generators, H.P.=horse-power, the date=when the road went into commercial operation.

In addition to the lines contained in the above table, electric street railways are stated to be in operation in no less than 79 other towns, but as no technical particulars are supplied we merely give the names of towns as below. It will be observed that in several instances there are two or three electric lines in operation in a single place :—Anniston (Ad.), Oakland (Cal.), Sacramento (Cal.), San José (Cal.), two lines ; Santa Cruz (Cal.), Hartford (Con.), Washington (D.C.), three lines ; Americus (Ga.), Atlanta (Ga.), Columbus (Ga.), Macon (Ga.), Rockford (Ill.), Streator (Ill.), Marion (Ind.), Cedar Rapids (Ia.), Clinton (Ia.), Kansas City, Lexington (Ky.), Louisville (Ky.), Portland (Me.), Cumberland (My.), Brockton (Mass.), Gloucester (Mass.), Lynn (Mass.), Nateck (Mass.), New Bedford (Mass.), Newburyport (Mass.), two lines ; No Adams (Mass.), Pittsfield (Mass.), Quincy (Mass.), two lines ; Salem (Mass.), two lines ; Whitman (Mass.), Worcester (Mass.), Winona (Ma.), Kansas City (Mi.), St. Louis (Mi.), five lines ; Anaconda (Mont.), Great Falls (Mont.), Helena (Mont.), Jersey City (N.J.), Newark (N.J.), Orange (N.J.), Paterson (N.J.), Brooklyn (N.Y.), Buffalo (N.Y.), Elmira (N.Y.), Hudson (N.Y.), Oswego (N.Y.), Syracuse (N.Y.), Tonawanda (N.Y.), Asheville (N.C.), Cincinnati (O.), two lines ; Columbus (O.), Newark (O.), Springfield (O.), Toledo (O.), Portland (Or.), two lines ; Beaver Falls (Pa.), Braddock (Pa.), Allentown (Pa.), Lancaster (Pa.), Shamokin (Pa.), Providence (R.I.), Chattanooga (Ten.), two lines ; Johnson City (Ten.), Knoxville (Ten.), Memphis (Ten.), Dallas (Tex.), San Antonio (Tex.), two lines ; Waco (Tex.), Salt Lake City, two lines ; Anacortes (Wash.), Fairhaven (Wash.), New Whatcom (Wash.), two lines ; Seattle (Wash.), two lines ; Spokane (Wash.), Spokane Falls (Wash.), Wheeling (West Va.), Marinette (Wis.).

The British East Africa Company's Land Lines.—This Company's land line is complete from Mombasa to Lamu, *viâ* Malindi, Golbanti (Tana River), and Witu, a distance of about 200 miles.

THE DEFLECTION AND CONTROL OF GALVANOMETERS.

BY E. TREMLETT CARTER.

The observation of the conditions of electrical stress which produce and limit the amount of deflection in any measuring instrument is an interesting and profitable one ; and it is proposed in this Paper to make a short study of the sources of the energy which produces the deflection in magnetic and thermal galvanometers, whether for measuring current or voltage. It is well known that two forces are concerned in the deflection ; one, the electrical or magnetic force of the quantity measured, which is caused by the coil or heated wire ; and the other the controlling force, which is variously produced by magnetic, gravitational, or other elastic forces. In most instruments the controlling force has to bring the pointer back to zero when the current ceases ; but there is an exception to this rule in the Cardew voltmeter type, in which the deflection is *produced* by the controlling spring and *cancelled* by the contracting wire. In any case, however, there is some transfer of energy when the deflection is being produced or cancelled ; and the source and destination of this energy form a very interesting inquiry. In an ideal instrument the whole of the energy which produces the deflection would be given back when the pointer returned to zero. But, in practice, owing to the imperfect elasticity of the deflection—through friction—the energy is only partially restored. The frictional resistances are opposed both at the forward and at the return motion of the pointer, causing a waste of energy on each occasion.

The energy which is temporarily expended when the deflection is being made must not be confused with that constant expenditure which takes place the whole time the instrument is in circuit. The two have no necessary relationship. The mere $C^2 R$ energy does nothing useful—neither in a magnetic nor in a thermal instrument. It may at first sight appear that the $C^2 R$ function does some useful work in a thermal galvanometer ; that, in fact, it supplies the heat by means of which the deflection is produced. But this supposition would be erroneous. The energy which does the work of the deflection is actually put into the instrument when it is manufactured, namely, at the moment the tension of the controlling spring is brought to the required amount. The *resilience* of the spring is a continual store of energy which is partially and temporarily drawn upon whenever a deflection takes place. This is restored to the spring in full amount when the heated wire cools and contracts. If we trace the passage of this energy from the instant it leaves the spring to the instant it gets back again, we shall follow a thermodynamic study of peculiar beauty. It is well known that all substances which expand on the addition of heat have their specific heats apparently raised by being subjected to increased external pressure, and lowered by being placed under tensile stress. The reason is that in the former case the expanding body does external work against the compressive force, while in the latter case the stress expends some energy in heating the expanding body. On this account, if a thin wire is heated by the passage of an electric current it will take less energy from the current, and will take less time in rising to its limiting temperature if it is under tension than if it is slack. Some of the stored heat of the wire is due to the current, but some of it is due to the expenditure of resilient energy under the relaxation of elastic stress of the spring which holds the wire tight. When the current ceases and the deflection is returning to zero, the conditions are reversed. The contracting wire expends heat on the tension spring, restoring its lost resilient energy ; and, in the ideal instrument, the amount of heat which will thus be converted into work will equal the energy originally taken from the spring. Thus it will be seen that the true $C^2 R$ function has nothing to do with the source of energy which causes the deflection. If the stress-strain diagram of the hot wire of such an ideal instrument be plotted, the curves representing a complete cycle will enclose no area ; but in an ordinary instrument this would not be the case. In such the curve of deflection would lie nearer to the axis of stress than the curve of restoration to zero ; and the area enclosed would represent loss of energy on account of

Hosted by Google

friction, pretty much as the area of the Ewing-cycle represents hysteresis losses.

In an electro-magnetic galvanometer the source of energy of the deflection is the electric circuit, but not through the medium of the dissipation function. The medium of exchange of energy is an electromotive force which is set up in the circuit when the needle moves. In a forward deflection there is a back electromotive force, which takes some energy from the circuit; while in the return of the deflection to zero there is a helping or forward electromotive force which restores this energy to the circuit from whence it had been taken. During the deflection this energy exists potentially in the controlling mechanism. Thus, if there is a bar-magnet control, the energy is stored magnetically in the ether; if there is a spring control, the energy exists as resilience of the spring; while if there is gravity control, the energy exists as a stress—*where?* Would that we could say where! *Is* it the ether?

MR. BALFOUR ON TECHNICAL EDUCATION.*

On Monday night Mr. A. J. Balfour distributed the prizes to the successful students in the Manchester Municipal Technical School and the School of Art. It was, of course, expected that he would make a speech; and he made one. It is scarcely possible for a man so able, and holding a position so prominent, to say much, or indeed anything, in public that does not deserve attention, and accordingly very considerable prominence has been given to his utterance on Monday night. But it is very easy to attach much more importance to his words than they deserve, or than, indeed, he would himself claim for them. His knowledge of the subject is limited; he was called in to bless, and if he had not blessed, his hearers would have been disappointed. It is obvious, too, that the facts (?) were all gathered from those earnest spirits who believe that the regeneration of commercial England is to be effected by technical education. Had a less important person spoken we should have kept silence, but the prominence of the event challenges criticism; and here, before going further, it is well to say that we have not one word to urge against the Manchester School of Art, nor, indeed, against its technical school. We have a quarrel, but it is solely with those who advocate the spread of technical education on wholly erroneous grounds, and support their contention with arguments the truth of which they have never attempted to prove. That technical education may be of service we do not care to dispute; that it can do the work, or has ever done the work, claimed for it we emphatically deny.

The principal assumptions on which Mr. Balfour based his speech are that technical education enables the foreigner to compete with us; that if we want to maintain and extend our supremacy we must adopt and extend the principle of technical education; and that although it was quite possible in times past for men who had no scientific training to invent and even discover, it was no longer possible for them to do anything of the kind. Much more space would be required than it is necessary to devote to the subject, to deal with these propositions in minute detail. Concerning the first, it suffices to point out that it is by no means clear that our foreign competitors *are* beating us. If they are, it is simply because so many markets are closed to us by hostile tariffs, and because wages are higher in Great Britian than they are in any other European country. With lower wages and free trade, or even with free trade alone, we could set all competition at defiance, and technical education on the continent of Europe would certainty not prevent us from beating all competitors. Concerning the second proposition, it is enough to say that, notwithstanding repeated challenges, no one has been able to adduce facts to prove that technical education has enabled Germany, or France, or Belgium, to excel us in manufactures or in engineering. No data whatever are supplied on this most important aspect of the question by any writer or speaker. We are met on every side by cloudy generalities with which it is impossible to deal, and which only evoke the ridicule of a large number of men engaged in manufactures and trade. When an adequate attempt has been made to prove that the manufactures of Germany, France, or Belgium are better than ours, and that they are better because of the prevalence of technical schools, we shall be happy to reconsider our position, but not before. There remains, then, to be dealt with only one section of Mr. Balfour's speech, that, namely, in which he urges the theory that it is to technical education we must look for future scientific developments in manufacture. "I think," said Mr. Balfour, "if you study the industrial and scientific progress in this and in other countries, you will find that up to a comparatively recent period theory has always lagged behind practice: you will find that it was not the theoretical but the practical knowledge of men engaged in the workshops, of men engaged in the actual industries of the country, which produced the inventions and made the discoveries which it was afterwards the business of the scientific man to explain and, if need be, to develop. The science of thermo-dynamics was in a very undeveloped condition when Watt invented the steam engine; and if it were worth while, and if I had the requisite knowledge in detail, I might go over each of your great industries to show that the science of the subject did not precede, but, on the contrary, succeeded, the practical knowledge of the subject, and that, therefore, in those days the theoretical education now given in your technical schools could not by any possibility have brought forth the great practical results which we now hope from it with some confidence." In this passage Mr. Balfour stated in well-chosen language the truth for which we have all along contended. But he did not stop here. He went on to explain why technical schools were, in his opinion, now wanted. "But observe," he said, "how greatly this is changed, at all events in some departments of industry. Perhaps the most striking example that I could take would be in the recent developments of electrical science in connection with the recent developments of industries founded upon that science. There you have science constantly, not following in the track of practical invention, but preceding and suggesting the practical inventions which proved to be based, and are based, upon theoretical knowledge, and this change, most clearly shown, perhaps, in electrical science, but surely shown also in engineering, chemistry, and a hundred branches of manufacturing industry—this truth, to which I have called attention, is becoming more and more true of all the industries in which we are engaged." Here, says the *Engineer*, we join issue with Mr. Balfour. It is just as true now as it has been at any time, that science follows in the footsteps of practice. Not a single improvement worth the name has been effected in steam-engines by professors; in other words, by men whose theoretical attainments are beyond question. To take a more recent instance, oil engines. These machines represent a new and most important branch of trade and manufacture. Their construction has involved new applications of thermo-dynamics. But the oil engine did not originate in the laboratory. It has not been invented by a professor. It has not sprung from the brains of a technically-educated Frenchman or German. It is purely the product of the brains of English mechanical engineers; and at this moment professors are toiling after these engineers, and vainly attempting to predicate what must happen, in which they are usually mistaken, and to enunciate laws which are usually wrong. Mr. Balfour was no doubt sorely perplexed to find a subject which could support his contentions, and he not unnaturally pitched on electricity; but he did this simply because he has not watched the progress of events. It is quite true that various discoveries of more or less importance have been made in the laboratory, but they remained utterly barren and useless until the engineer took them in hand. The man of science gave no help whatever to develop them into methods of adding to the comfort, the wealth, or the commercial prosperity of the nation. His function in the arts is to consolidate, to arrange, not to create. Take, for example, multiplex telegraphy or the electric light. What has the laboratory or technical education done for these things? If Mr. Balfour were only behind the scenes, if he only knew how absolutely dependent the man of pure science is on the engineer for the facts on which alone true theory can be based, he would have confined himself to generalities and carefully avoided the particular.

It is not only that the man of pure science does not originate. We go further, and say that scientific training is fatal to originality. There are, of course, men of genius who triumph over all obstacles, and convert them into stepping-stones to success. But to the great mass of mankind a scientific training is, as we have said, a bar to advancement. Nor can it be otherwise. If we look to the history of human progress in the arts, it will be found that it has been based on the method of trial and error. All our arts have been evolved, not created. But it is impossible to work in this way without making mistakes. Yet the scientific method is intended to make mistakes impossible. A single example to illustrate our meaning is all that we can find space for. It can be proved beyond all fear of contradiction that the efficiency of expanding steam is entirely independent of the number of cylinders in which it takes place. Now, a man carefully taught thermo-dynamics a quarter of a century ago would not only not dream of using a compound or triple-expansion engine himself, but he would laugh at anyone who did. Accordingly, we find that the modern marine engine not only did not originate with the man of scientific training, but that it was made in spite of prognostications that it must be a failure. Many other examples of the same truth will no doubt suggest themselves to our readers. We remember once hearing it said of a man of high scientific attainments in reply to the question, "How is it that X. originates nothing?" "Oh, you know, a man in his position cannot afford to make a mistake." It is, however,

* From the *Engineer*.

Hosted by Google

only fair to say here that the real men of science are those who claim least for themselves, and attach a value to science, as an aid to commerce, so small that it would astonish the noisy advocates of technical schools. Finally, we would conclude with a word of caution to our readers. No phrase has been more misused or perverted than "technical education." In the fullest and highest sense, it is essential to the well-being of this country, and we do not hesitate to add that there is no country on earth in which it has been carried to such perfection. But it is not in technical schools that it can be learned. It may be a very good thing that boys should be taught a little science and a little manual skill in these places or it may not, but it is a soul-depressing figment of the imagination, that Great Britain must depend in the future on such establishments for her commercial existence.

THE INDIA-RUBBER TRACTS OF UPPER BURMA.*

Some interesting information has reached us in regard to the india-rubber forests and trade of the Bhamo District of Upper Burma. This information is not complete, and may be in some few minor respects faulty; but we believe it to be fairly accurate in the main, and at a time when there is some pessimism displayed as to how long supplies of india-rubber will hold out, the matter is one of public interest. The information referred to tells us that practically all the india-rubber that is put on the market in Bhamo is extracted from the *ficus elastica*. This extends from the latitude of the Indawgyi Lake northwards, and is said by the Kachins to be found as far north as the small Shan State of Khampti on the Upper Irrawaddy westward, and north-west it extends to Assam, but it is not at present known to grow naturally east of the Irrawaddy. The trees are usually scattered either singly or in groups of two and three in dense evergreen jungle, and they are, as a rule, separated by long distances. For instance, on the Jade Mines road, from Nanyong to Numnuyang, 44 were counted in 12½ miles, and this number included three dead trees and seven seedlings. This, too, was a comparatively large number, the average of all the countings made by one forest officer being only one tree for every 10¼ acres in the forests on the northern watershed of the Tanai chaung. The Kachins remark that the district referred to fairly represents others, and from the figures quoted, it is judged that it would be impossible to form forest reserves for *ficus elastica* alone, as it would not be worth while to take up and protect the area necessary to give any large yield of rubber. It is reported that the forests on which the trees are found consist of a dense evergeen jungle, the undergrowth being, as a rule, particularly thick and impassable, composed of small bamboos and evergreen shrubs, besides canes of every description. The rubber seedlings are invariably found growing down from the forks of light-foliaged trees, being unable to stand the dark atmosphere near the ground. The seedlings removed by the Kachins and planted near their villages seldom attain a height of more than from 60ft. to 80ft., whilst those growing naturally in the jungle and starting from a fork at a height of 70ft. or 80ft., and growing upwards and downwards by means of their aërial roots, frequently attain a total height from the ground of 130ft., thus having a very much larger surface available for cutting.

It may be remarked that the india-rubber tracts under reference may be divided into seven sections, but it is not necessary for our present purpose that we should particularise these. The most important section is north of the Tanai chaung. The area is drained by three streams, which help to facilitate transport. Roughly, the produce of all sections may be estimated at 200,000 viss (1 viss=3·6lb. av.) per annum. The transport of the cut rubber is in many cases the greatest obstacle to the exploitation of forests, as men have to go long distances, carrying all their requirements on their own backs, and able to count on getting absolutely nothing while on the hills. The way they work is as follows:—When the rubber is rolled up into balls they carry these down in bamboo baskets to a stream. Here they string the rubber balls together with canes passed through their centres, and thus form long lines of balls 15ft. to 20ft. in length. Then these strings are towed down stream, a number at a time, by means of a chest-band of woven cane. If the streams become too deep for comfort, small bamboo rafts are made and poled down. From other districts cost of transport is often much heavier, on account of the greater length of the land journey. In like manner, there is no uniformity in regard to prospects. While some districts have suffered from overworking, others are still but little used. The process of tapping varies, too, though it does not seem to be anywhere very skilful. In the Jade Mines tract the trees are cut from the very top downwards to the extremity of the smallest roots that can be found, and the roots are followed up underground to great distances. In the Chindwin District the rubber is extracted by more or less horizontal incisions made by two strokes of the ordinary Kachin da, one an upward cut at an angle of 45deg., and the other a similar downward cut. The cuts are made on the upper and lower surfaces of the branches, and the juice as it runs drops to the ground, which is not prepared for its reception beyond a slight clearing of the undergrowth. Of course, the result is that much of the rubber contains earth and rubbish.

From these few remarks it will be understood that the trade in india-rubber procured from Upper Burmese districts labours under various disadvantages. The quantity of rubber produced by two equal-sized trees, one on the hills and one on the plains, differs greatly. The former gives plenty of juice, but not much rubber. The Kachins know this, and as a consequence the quantity of rubber yielded by the tracts which are easily got at is falling off. Certain protective measures are necessary. Then again, the tapping needs to be performed more skilfully, and adulteration must be avoided. And even if all this can be done, needful reforms are not complete. The trade is in the hands of the Chinese, who are supposed to have grown fat on the profits. The pernicious advance system has been in vogue, but is now falling into disuetude. There appears, however, to be any amount of scope for cheating in the way of adulteration, false weighing, &c., and it is suggested that the Government should take a much more active part than it has yet done in regulating the trade; also that a duty of eight annas per viss should be levied. This, it is thought, could be done without stifling or diverting the trade. This is one of some importance. The price runs about Rs.410 per hundred viss in Rangoon, and the shipments from Rangoon during 1891 amounted to some 305 tons. The rubber from *ficus elastica* is about the cheapest in the market, and, doubtless, with proper care, the trade could be developed. But at the present time there appears to be difficulty about protecting the trees, as well as about getting pure rubber and preserving it from adulteration. Now that the subject has received official consideration, however, some steps will probably be taken, and it is possible that Upper Burma will solve the problem that has recently been suggested, "Will supplies of india-rubber soon be exhausted?"

* From the *India-Rubber, Gutta-Percha, and Electrical Trades Journal.*

THE ENGINEERING DETAILS OF THE NEW YORK-CHICAGO LONG-DISTANCE TELEPHONE LINE.*

BY JOS. WETZLER.

Up to the time at which the New York and Chicago line had been contemplated, the longest sustained successful telephonic transmission had been about 500 miles, and it was, therefore, a matter of no small consideration, and one the importance of which the American Telegraph and Telephone Company well recognised, that the operation of a line almost twice this distance should be successful at the very start. The previous experience of the Company stood it in good stead, but the rules which had been laid down for the calculation of the size of wire required for the transmission of speech had been found to be at such variance with the actual practice of the Company that its engineers were necessarily obliged to observe the greatest caution in their recommendations. The most commonly accepted rule for telephonic transmission is that laid down some few years since by Mr. W. H. Preece, which is as follows:—

When K R	=	15,000,	speech impossible.
,, ,,	=	12,500	,, possible.
,, ,,	=	10,000	,, good.
,, ,,	=	7,500	,, very good.
,, ,,	=	5,000	,, excellent.
,, ,,	=	2,500, or under,	perfect.

This rule, it must be pointed out, is entirely empirical, and as such, as frequently turns out to be the case, is only safely applicable to circuits whose length is within the limits of those by which the rule was formulated. As proof of this we may remark here that the telephone line between London and Paris was built according to this rule, and the K R constant of 7,500 was adopted. When the line was finished it was found that transmission over it was very much better than the formula indicated, which went to prove that the rule apparently did not apply to that particular line. But long before the completion of the Paris-London line, it was well-known to the engineers of the Long-Distance Company, that this rule was not generally applicable, for the reason that the circuits at their command showed that transmission was possible over lines having a very much higher K R constant. Thus among the experiments tried by them was the coupling up of lines aggregating in length

* From the *Electrical Engineer* of New York, December 14th, 1892. Abstract.

Hosted by Google

from 650 to 1,100 miles. The results obtained are shown in the following table :—

650 miles,	transmission excellent	K R = 31,000.
750 ,,	,, good	K R = 45,000.
885 ,,	,, poor	K R = 62,000.
1,100 ,,	,, none	K R = 91,000.

These experiments were made with a "solid-back"* transmitter, and three cells of Fuller battery, the usual equipment of the long-distance telephone set.

According to the formula enunciated by Mr. Preece, it would require a wire weighing nearly 2,000 pounds to the mile in order to communicate with Chicago, and it was not to be wondered at, therefore, that the engineers of the Long-Distance Company hesitated in applying this rule. The result of their own experience, however, was such as to give them confidence in the selection of a greatly reduced size of wire, and after due consideration it was determined to select a No. 8 B.W.G. wire, having a diameter of 0·165 inch, and weighing 435 pounds to the mile. (See comparative sizes of the theoretical and actual wire depicted in Fig. 1, which we have taken the liberty of adding to Mr. Wetzler's excellent

Fig. 1.—*a*. Wire which should have been used on the New York-Chicago Telephone Line, according to the K.R. Law. *b*. Actual wire used.

article.) This wire has a resistance of 2·06 ohms per mile, and a capacity of 0·0158 microfarads per mile, with wires strung 35 feet above the ground. The thousand miles, practically representing the distance between Chicago and New York, has a K R constant of 32,000. Yet, notwithstanding this enormous excess over the limiting figure laid down by Mr. Preece, it was adopted and the line built. The results obtained are now well known, but even before the building of the line was begun the engineers of the Company were firm in the conviction that it would prove to have such excellent speech transmitting qualities that it would give a sufficient margin to make it possible to add on other lines at the end, and possibly secure communication to cities beyond Chicago, such as Minneapolis, St. Paul, and St. Louis ; while, on the other hand, it would leave large margin for the attachment of local lines within a radius of 100 miles from Chicago.

taken the resistance of one of the wires of a metallic circuit, measured in ohms, and multiplied it by its electrostatic capacity measured in microfarads, to ground. The difference evidently is one of method only, the result being the same. It might be well to point out here that one wire measured against its mate, as done in the calculations of Mr. Preece, is never found to be exactly one-half of the capacity when measured to ground, being usually found to be from 60 to 65 per cent. of that quantity.

The building of the line having been determined upon, the questions of the details of construction to be adopted were given most exhaustive study. In this respect the experience of the Company in its past work has also stood it in good stead, with the result that it is fair to assume that the construction adopted will afford a line of the most permanent character.

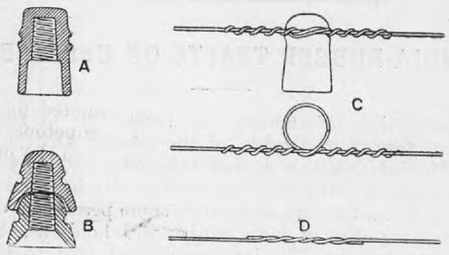

Fig. 2.—Details of construction on the New York-Chicago Telephone Line.

The line is built of standard poles 35ft. long, of the best quality of live green cedar wood peeled, and the knots trimmed close This length of pole permits it to extend not less than 26ft. above the surface of the ground. The cross-arms employed are of thoroughly seasoned, straight-grained Norway pine, 10ft. long, $3\frac{1}{4}$in. thick, and $4\frac{1}{4}$in. deep. These cross-arms are given two thorough coats of metallic paint, and are braced with two galvanised iron braces, which are attached to the cross-arms by means of galvanised iron carriage-bolts. These cross-arms are fastened to the pole, not in the usual way, by means of fetter drive screws, but by a galvanised iron bolt, the pole being bored for the purpose, and the bolt passing entirely through. Washers under the head and nut prevent abrasion of the cross-arms and the pole.

The insulator pins are made of clear split locust, $1\frac{1}{4}$in. in diameter. The type of insulator employed is the regular standard white glass

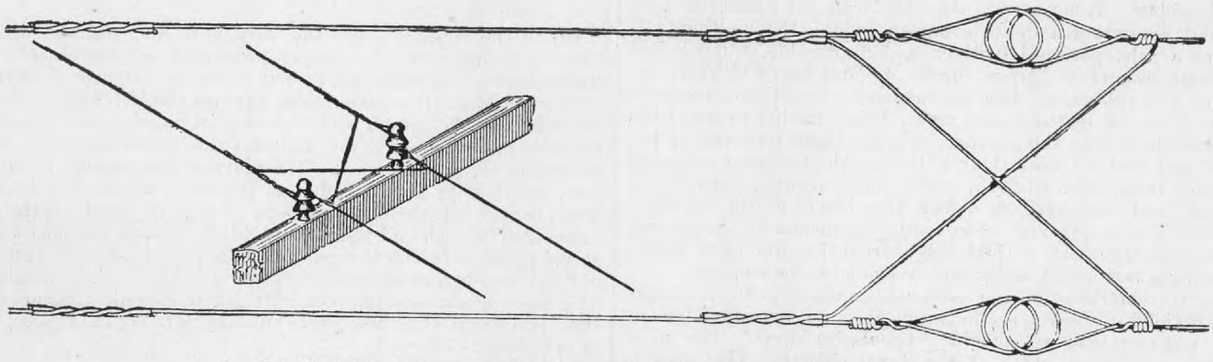

Fig. 3.—Method of transposing wires on the New York-Chicago Telephone Line.

As another proof of the inadequacy of the transmission formula, as laid down, it is only necessary to consider the following K R constants for lines which are now, and have been for some time, in daily operation, as follows :—

Boston and Washington.....	R=26,250
Boston and New York	K R=12,100
New York and Philadelphia	K R= 2,000

From the above it is evident that, while the lower figures giv n by Mr. Preece agree thoroughly well with the results obtained on the long-distance lines, the higher figures are greatly at variance with it, the circuit between Boston and Washington, for instance, exceeding Mr. Preece's figure for speech "impossible" by nearly 75 per cent.

As some question might be raised as to the manner in which the K R constant is here calculated, it might be well to point out the fact that Mr. Preece multiplies the total resistance of the circuit by the capacity of one of its wires measured against its mate, and estimates that the capacity of one wire measured against its mate is one-half of what it would be if measured to ground. In the calculations made by the long-distance engineers, they have

* See *The Electrician*, December 2nd, p. 119.

American Telegraph and Telephone Company's insulators (A, Fig. 2). For the guard wire the 20oz. Western Union double-petticoat insulator, without petticoat, is used. The transposition insulator is of the Hibbard pattern, of white glass, and is shown at B, Fig. 2.

On the corner poles guard irons are employed. Every tenth pole is furnished with a lightning rod made of No. 6 galvanised iron wire. These rods are fastened to the pole every two feet by iron staples extending from the top to the bottom, and at the latter end they are given two hand turns. In ordinary good ground the poles are set at distances of 130ft. to a depth of 6ft., and on curves to a depth of $6\frac{1}{2}$ft. The method of tying the wires is shown at C, Fig. 2. Here it will be noticed that one side of the the wire passes around the line wire and makes five complete turns. The joints in the copper line are made with McIntire sleeves, each sleeve being given three complete twists, as shown at D, Fig. 2.

In laying out a telephone line great care must, of course, be taken to avoid cross-talk and other disturbing influences, which militate so much against clear enunciation, and make wires noisy. For this purpose it is necessary to transpose the wires at proper intervals, and to accomplish this transposition insulators are employed. Fig. 3 shows the method of carrying out the transposi-

Hosted by Google

tion. It will be noted that the line coming from the left is dead-ended on the upper insulator, and continued by means of a cross-over connector to the neighbouring line, its mate. This line is also dead-ended on the other upper insulator. In the same way the other two sides are joined so that the position of the conductor on each side of the cross-arm is reversed.

The present line carries two cross-arms, which will eventually carry 10 wires each. The line passes through, or is connected by short branches and loops with, the most important cities between New York and Chicago.

Credit must be accorded to the enterprise and management which has made the New York-Chicago line a possibility, but we cannot close this description without a brief mention of those who have had immediate charge of the work and have brought it to a successful completion. Mr. E. P. Meany, assistant general manager of the Long-Distance Company, has had charge of the construction work of the entire line, and F. A. Pickernell, engineer of the Company, has had general charge of the electrical and mechanical working out of the system; while Mr. A. S. Hibbard, the general superintendent, has had charge of its operation and maintenance. The Company is to be congratulated on the possession of the services of men so thoroughly competent, and whose work will, no doubt, prove of permanent value to the profession at large.

THE OBJECTIVE REPRESENTATION OF HERTZ'S RESEARCHES ON ELECTRICAL RADIATION.*

BY L. ZEHNDER.

The small sparks which Hertz obtained in the secondary conductor in his experiments on rays of electric force are not immediately suitable for representation to numbers of people, because they emit very little light. It is true that sparks can be obtained about 6m. away from the reflector and about $\frac{1}{3}$mm. long, and these sparks can be seen about 3m. further off in a darkened room, but these can only be seen by a very limited number of people. Many devices have, therefore, been employed to make the Hertz effect visible.† The author has endeavoured to attain this object by making the Hertz sparks cause the discharge of a high-pressure set of accumulators through a Geissler tube. The brilliant light of the tube, which continues so long as the primary discharge is continued, is a very impressive method of showing the experiments of electric radiation and reflection. Hertz has himself lately published an account of an experiment in which he has caused the discharge of such a high-pressure battery through a minute air gap by means of ultra-violet light-rays, a method which has some analogy with the experiments about to be described.

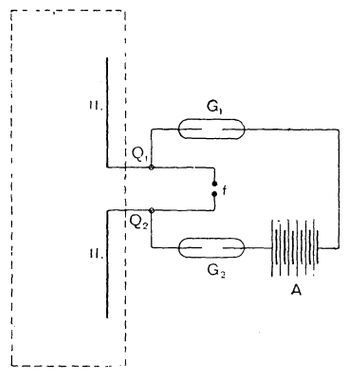

FIG. 1.

The author employed in his researches a reflector with its primary and secondary conductors in the position described by Hertz; the secondary conductor consisted of two brass plates, each of 50cm. long, 5cm. wide, and 1mm. thick. The secondary of the Ruhmkorff coil gave very good sparks of 0·7cm length when worked with the very rapid Deprez interruptor. The battery consisted of a set of 600 small Planté cells, and was coupled in series with a megohm, so that very small currents passed through the Geissler tube, which could thus be worked for hours together.

The results of a few preliminary experiments may be of interest. The first successful experiment in obtaining effects of the electric oscillations in the secondary conductor on the discharge in a Geissler tube, was with the arrangement shown in Fig. 1. II II are the secondary conductors in the focal line of the reflector. Q_1 Q_2 are mercury cups, G_1 G_2 are small Geissler tubes about 4cm. diameter, having their electrodes fairly close together; f is the Hertz spark gap, and A the battery. The spark gap was so regulated that, when the battery was cut off, small sparks jumped across; then the battery was put on and adjusted to such a potential difference that another cell or two caused sparking through the circuit $G_1 f G_2$, the potential difference being thus just too little to start the current. If, now, the Hertz spark was started at f, the current from the battery immediately broke down the resistance of G_1 and G_2, and the glowing of the tubes showed that the Hertz spark had occurred.

The spark gap was now introduced into the tubes themselves. First, a tube containing a spark gap of definite length was slowly exhausted and the behaviour of the spark noted at intervals; the brilliancy of the spark appeared to diminish with the pressure of air. Then the pressure was reduced to 1mm. of mercury; and in order to produce a very small sparkgap, thick platinum-tipped copper wires of about 5cm. length were sealed into the tube and made to touch when hot. On cooling, the copper wires contracted more than the glass, and caused an almost infinitesimal gap between the points, which, of course, increased as the tube cooled. While cooling the secondary, sparks were passed through the gap in the exhausted tube. At first the spark looked just like the ordinary Hertz spark, but, as the wires drew further and further apart, there came a critical point at which the bright spark disappeared. If, now, the tube was looked at in a darkened room the space in the neighbourhood of the electrodes was found to be aglow, the phosphorescence being greatest at the electrodes, and spreading several millimetres on every side. This glow is no doubt the well-known kathode light, and it appeared to be very nearly symmetrical with regard to both electrodes. The anode light could probably not be seen, as it was so near as to be masked by the brighter kathode. It was remarkable that the change from spark to glow occurred quite suddenly when the electrodes reached the critical distance apart. The glow could be made between electrodes further and further apart as the Hertz reflectors were put nearer and nearer together.

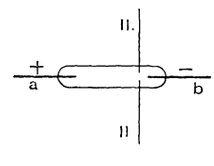

FIG. 2.

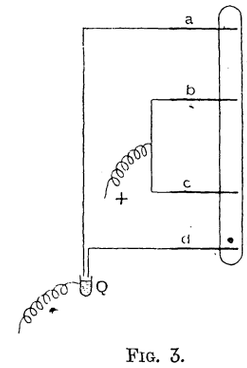

FIG. 3.

The author then proceeded to seal in the same tube electrodes both for the direct-current discharge and the Hertz spark, as shown in Fig. 2. a and b are the electrodes, II II the Hertz secondary conductor. The spark gap was placed near the kathode, since it is known that in the neighbourhood of this lies the greatest resistance of the air path; and by breaking this down by means of the Hertz spark the greatest possible diminution of resistance would be obtained. It was found that if, as before, the potential difference between a and b was adjusted to be just too small to start the current, the Hertz spark would cause it to start if the spark was taking place in a gap sufficiently wide to cause it to take the form of the glow described above, but not otherwise. The Geissler tube continued to glow until its circuit was broken. It is, therefore, only the glow discharge of the Hertz secondary which is capable of so diminishing the resistance of the air path in the Geissler tube as to start the battery current.

The next experiment is shown in Fig. 3. Two sets of electrodes, $a\,b$ and $c\,d$, were sealed into the same tube, a and b being slightly wider apart than $c\,d$. Between this latter pair was the spark gap f. By means of a mercury cup, Q, either pair of electrodes could be coupled up to the battery. If $a\,b$ were coupled to the battery, so that a discharge was set up, no current would pass from c to d if also coupled up; but if, and so long as, Hertz sparks were passing at f, the glow took place between c and d. Thus, by concealing the tube $a\,b$ from sight, the part $c\,d$ would light up whenever a Hertz spark was passing at f. The tube gradually became useless, as after a time the resistance of the gap $a\,b$ became less than $c\,d$.

Many experiments were made with the arrangement shown in Fig. 4. The secondary conductors II II were fastened to the tube B, whose electrodes $a\,b$ served for the accumulator discharge. A is the accumulator, W_1 and W_2 high resistances, m and n switches.

* Abstract from *Wied. Ann.*, No. 9, 1892.

† *See* Lucas and Garrett, *Phil. Mag.* (5) 33, p. 299, 1892, and *Wied. Ann.*, Vol. XL. and XLIII.

Hosted by Google

The tube was 0·8cm. diameter inside, and the electrodes were 5cm. apart. The spark gap was at *f*, near the electrode *b*, which generally served as kathode, and the gap was estimated at $\frac{1}{50}$mm. In order to prevent the change of resistance of the tube described in the last paragraph, a certain amount of metallic sodium was passed into the tube by means of the electrode *e*, which absorbed the oxygen remaining in the tube after exhaustion.* The pressure was 1·2mm. of mercury. The resistances W_1 and W_2 were tubes containing a solution of cadmium iodide in amyl

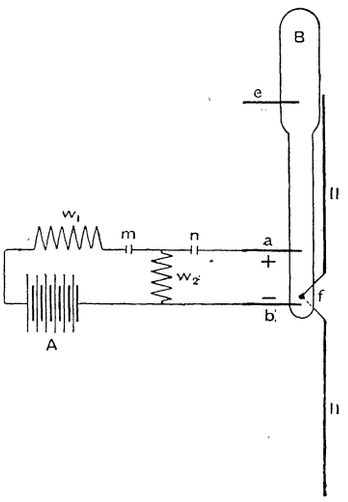

FIG. 4.

alcohol, and were adjustable. W_1 in series adjusted the strength of current, W_2 in parallel adjusted the potential difference on the electrodes. By means of this arrangement the passing of the Hertz spark can be shown very well, using reflectors up to 8m. off. The battery discharge, which is started by the Hertz spark, can be seen easily in a room into which no direct sunlight enters, fully 10m. away. By use of the resistances W_1 and W_2 the potential can be so accurately adjusted that the battery discharge both starts and stops with the Hertz discharge.

The author describes some experiments which tend to show that, owing to the variability of the potential difference of an induction coil, it is not equally as well suited for these experiments as a high potential battery; but he says it may be used where the battery is not available.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 2, 1892.

The Westinghouse Glow Lamp.—It has just been announced that the Westinghouse Electric and Manufacturing Company has fixed its prices for the new two-part lamps, the manufacture, sale and use of which, it is claimed, do not infringe the Edison patents. The list prices will be 35 cents for 25 and 20 c.p. lamps, and 30 cents for 16, 10 and 8 c.p. lamps. The discounts will be from $2\frac{1}{2}$ to 10 per cent., according to the quantity ordered at one time, and 10 per cent. regularly to its central stations. The allowance for delivery at its factories of the glass parts of such lamps will be 10 cents each, so that the net price of the 16, 10 and 8 c.p. lamps, which form nine-tenths of those used, will be about 17 cents each. It is estimated that the saving to a central station by the return of the glass parts of the lamps and the low prices of the new lamps will equal nearly 1 per cent. dividend on its capital stock. Although the time set for the placing of this lamp on the market has arrived, it has not yet appeared. That the prices for it have been fixed, however, is taken to be sufficient indication that the arrangements for its manufacture are pretty well settled. A good deal of interest has been aroused among lamp experts regarding the possibility of maintaining a sufficiently good vacuum by means of the processes which outsiders have been given to believe are to be used by the Westinghouse people. An interesting point has been brought up in connection with the advent of the separable lamp. It seems that the original application for a patent on this device was rejected a number of times by the United States Patent Office, on the ground that the idea was not new, and that it was in constant use in such well-known apparatus as glass-stoppered bottles. Later, however, a number of patents were issued on a variety of lamps embodying this principle, but it is claimed that no patent has yet been granted on the fundamental idea. Such patents as were issued, however, are now controlled by the Westinghouse Company, but it has been intimated by reliable authorities that the General Electric Company may take the matter up and endeavour to secure a patent on the original application for a separable lamp. This, it is claimed, it is possible to accomplish, on the ground that the device has not been in public use. This is an interesting point which may have considerable bearing on the future of the lamp industry in this country.

NEW YORK, *December* 9, 1892.

Electrical Literature.—Dr. John Hopkinson's "Collected Papers on Dynamo Electric Machinery and Allied Topics" has just appeared from the press of an American publishing house. It is a little strange that these papers have not been published in this form in England, as the demand for them must have been considerable, judging from the frequency with which they are quoted by writers on electric lighting machinery. An Electrical Encyclopædia is proposed in this country by Mr. Park Benjamin, who, as is well known, has for some time been the Editor-in-Chief of Appleton's Mechanical Dictionary. It is proposed to make a volume of about 1,000 pages, and it would probably be strictly an American book. Mr. Park Benjamin has just received from his agent in Italy a unique book; it is a copy of the first edition of Galvani's essay, "De Viribus Electricitatis in Motu Musculari," published at Bologna in 1791. It contains, in Galvani's own handwriting, the revisions and corrections which were incorporated in the second edition, published the following year. The work is, in any form, of extreme rarity, and a copy with the author's own corrections is, of course, of very great interest.

The Edison-Westinghouse Case.—The Edison-Westinghouse case has been going on this week in the United States Circuit Court of Appeals, before Judges Shipman, Lacomb, and Wallace. The arguments of the attorneys occupied three days, and were finished yesterday. It is expected that a decision will be handed down at an early date, probably before the end of the month or early in January. The case is attracting considerable attention, and the point at issue as to whether or not the General Electric Company's organisation is a violation of the anti-trust law is conceded to be an important one for that company. The case is watched with an interest second only to that shown in the big lamp suit, in which the decision was handed down by the same Court. It is asserted that a very strong point has been made by the Westinghouse Company in this matter, and that had it not already been admitted by this Company that it had an incandescent lamp to place on the market which would not infringe the Edison patent, the Court would undoubtedly regard the tactics of the General Electric Company, in seeking to control other branches of the electrical business by its monopoly of the incandescent lamp business, as injurious to general trade. The fact, however, that the Westinghouse people claim to have a lamp of their own, may convince the Court that the present methods of the General Electric Company will not, after all, injure the general business to any extent.

A Large Westinghouse Alternator.—A large alternating dynamo, said to be the largest alternating-current dynamo used in central station work in this country, is now in operation and under test at one of the stations in this City. It is a Westinghouse machine of 6,000 lights capacity. This, of course, will be exceeded by the World's Fair machines constructed by the Westinghouse Company, which are to be sufficient for a load of 10,000 lamps.

NEW YORK, *December* 17*th*, 1892.

The Edison Lamp Decision.—The chief event of the week in electrical circles is the handing down of the decision in the Edison lamp case by Judges Lacombe, Shipman, and Wallace. This decision, as was expected, is again in favour of the

Hosted by Google

Edison Company, although the Sawyer-Man people were successful in obtaining a limitation which compels the General Electric Company to sell lamps to the Sawyer-Man Company and its customers. This suit, it will be remembered, was on an appeal from the decision of the lower Court on the application of the Edison Electric Light Company for an injunction to restrain the Sawyer-Man Company from making or selling incandescent lamps. Regarding the question raised as to the propriety of the General Electric Company appearing before the Court as the real prosecutor, the Courts said that whether it is a trust contrary to law or not there can be no question regarding its right to control the patent in question, and it does not in reality enter into the discussion of the question as to whether the General Electric Company is or is not an illegal trust. The following paragraph from the decision indicates the conditions upon which the injunction is granted:—"The injunction order appealed from should be modified so as to cover only lamps made in infringement of the second claim of the patent, the other claims not having been infringed according to the adjudication of the Circuit Court or this Court. It should also contain a provision reserving the right to the defendant to move hereafter for the vacation, suspension or modification of the injunction upon proof of specific instances of refusal on the part of the complainants, or either of them, to supply the lamps of the patent upon terms reasonable under the circumstances of the particular case to the owners of electric light plants, which are modified before the rendition of the interlocutory decree of the Circuit Court sustaining the validity of the patent."

There is much speculation as to what will be the manner of dealing with the lamp companies It is known that some of them had already applied for permission to manufacture by the payment of a royalty. Whether or not any of the smaller companies will be allowed to manufacture or not is as yet unknown, and it is most likely that the new Westinghouse lamp—which is promised, but which, by the way, has not yet appeared on the market—may change to a considerable extent the condition of affairs, should it prove a commercial success. Some of the smaller companies could, doubtless, obtain from the Westinghouse Company a licence to manufacture the lamp, and, owing to the fact that it is much cheaper, would probably prefer to do so rather than manufacture an Edison lamp which could not be put upon the market at the same price. It is said that some of the new Westinghouse lamps are now in use in lighting the Administration Building at the World's Fair grounds in Chicago.

Obituary.—Mr. M. M. M. Slattery, the designer and patentee of the Slattery induction system, the patents for which are controlled by the Fort Wayne Electric Company, which is a licensee of the General Electric Company, died at Fort Wayne, Ind., on Wednesday last.

The Endowment of Commercial Electrical Research.—A Bill has been introduced in Congress by Senator Vest, of Missouri, for the purpose of securing an appropriation for the encouragement of experiments in the application of electricity to long-distance electric railways, to agricultural work, and especially to the proposed Chicago and St. Louis electric railway, the project of Dr. Wellington Adams. This Bill was referred to the Committee on Commerce. It is urged in favour of the Bill that the appropriation should be made because of the benefits which would generally result from the development of such a project as the more rapid transmission of mails. Whether or not the general government will see fit to take a hand in such work remains to be seen.

Apprentices.—A law has been recently passed in the canton of Neuchâtel, says *Industries*, on the subject of apprenticeship. By this law apprentices are placed under the supervision of competent authorities, delegated for that purpose by the communes, who are to see that all receive thorough instruction in their adopted callings, while the technical knowledge and professional aptitude of the apprentices are to be ultimately tested by an examination.

CORRESPONDENCE.

THE COST OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your issue of December 16th, while it contains letters enlarging on the desirability and difficulties of differential charges, contains also the description of a meter whereby all these difficulties appear to be overcome in any system of distribution in which separate wires to the meters can be economically laid. Mr. Scott's meter is, as far as I know, the first to practically embody a principle which appears to have been simmering in the minds of more than one engineer. It seems to admit of two methods of application:—The registering current may be maintained for the same time, but the intervals between successive currents may be changed in any manner; or the periodicity may be kept constant, but the duration of the current may be changed, as in the case of the steam admission in the latest type of Parsons' Turbine. Of course, any combination of the two methods might also be adopted, though for the sake of economy in the registering current it is desirable that its duration should bear only a small ratio to the total period. In the turbine a compounded electro-magnetic steam relay makes the period of admission dependent on the output of the generator, and it would probably be easy to devise an automatic control over the central station clock, which would make the duration or the periodicity of the registering current depend upon the total output of the station according to any pre-arranged law. The price of electrical energy could then be made automatically to vary as the nth power of the output of the station, "where n has any value, positive or negative, integral or fractional." It is clear that on this system the meters would not record Board of Trade units, nor could the energy employed be determined from the simple register of the meter. The dials ought, therefore, to be made to register directly in £ s. d.; a system which has the merit of being readily comprehended by the average mind, trained as it is in all our schools to work arithmetical problems of every description in money, though too often to the total neglect of all other kinds of units.

I do not think that the clauses against preferential charges in the Electric Lighting Acts will create any difficulty, as it may fairly be held that the undertakers do not "show any undue preference to any local authority, company, or person," when all are charged alike on the same sliding scale. The system will, however, render the testing of meters by the local authority a much more complicated business than it is at present, and one objection to the charge per unit being dependent on the station output at the time, instead of depending simply on the hour of the day or the season of the year, is that any large consumer by turning on his lights can alter the price for every other consumer. It may also be objected that the central clock places all the meters too much under the control of the staff at the supply station, but this difficulty may easily be met.

Major Flood-Page alludes to a very serious question which the Electric Lighting Companies will have to face at an early date. I am interested in an institution which provides its own electric supply, the plant being at present arranged for about 20 kilowatts, though this will have shortly to be more than doubled on account of extensions of the building. It is convenient to blow off the boiler on Saturday afternoon, but it is generally necessary to use a few lights on Saturday evening, and there are no accumulators on the premises. In the summer, too, lights are frequently required for short periods which scarcely justify firing the boiler when no steam is required for heating purposes. The institution is within the compulsory district of a public supply company, and it was obviously far cheaper to pay a fixed charge of something like £5 per annum for the hire of a meter and transformer, in addition to the usual rate of charge for current, than to make a special arrangement for the production of current on the premises at these exceptional times. At the same time, it is obvious that the Institution can be but a poor customer to the supply company, and the use of the current between 5 p.m. and 9 p.m. on Saturdays is certainly not conducive to the interests

Hosted by Google

of the Central Station. In this particular case the company was asked to supply only a six-kilowatt transformer, and the use of the alternating current for experimental purposes may, perhaps, make a reasonable return on the expenditure of £60 to which the Company was put in laying a special main for 150 yards. But other institutions in which steam is employed for heating or for power may adopt the same system, if only to obviate the necessity of duplicating their electric lighting plant to provide against break-down, and may not show the same consideration to the Electric Lighting Company. For a supply station to be liable at any time to be called upon for 1,000 lights in a large hotel, hospital, or other establishment, merely because the private machinery has broken down, or the engineer in charge wishes to wash out and inspect his boiler, is a hardship against which provision should be made. WM. GARNETT.

GILBERTIANA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Both my friends, Mr. Dredge and Dr. O'Reilly, who write you on page 223, have fallen into the same singular misapprehension respecting my reference to Messrs. Wiley and Sons, of New York, the firm that has gained for itself an evil notoriety by its issues of the commonly-called pirated edition of Ruskin's works, and which is announced as about to publish an American edition of "De Magnete." My statement that the Gilbert Club had nothing to fear from a publication issuing from this notorious house referred—I thought obviously—to the quality of their publications. The cheap imitations which they brought out of Ruskin's beautiful books showed to what degradation artistic work may be brought. No true lover of art would ever dream of looking for figs from such thistles. The lowered artistic and typographical quality of such productions was the point of my reference, which only incidentally touched the question of the well-known literary piracy. There is, therefore, no need to reply further to Dr. O'Reilly for his defence of the literary highwaymen who were so generous as to offer to their victim a percentage of their ill-gotten gains, though the true history of Mr. Ruskin's indignant refusal is not yet forgotten on this side of the water.

Now, as to Mr. Dredge's rambling story. I have met Mr. Mottelay but once, when he saw me at my laboratory for about half-an-hour, in the interval between the delivery of two lectures. He left me with the impression that he would come again for a fuller exchange of ideas; for I had told him that I wished to show him my library and various Gilbertiana. For some six weeks (for he left me no address) there lay on my writing-table ready for him a copy of my biographical tract on Gilbert, and a membership form in the Gilbert Club ready for his signature. He told me that before the Gilbert Club began its work he had had the intention of making a translation of "De Magnete," and had already begun it. I told him that he was not the first, as I knew of two or three others who had independently begun translations years before. As to the "astonishing inaccuracies" of which Mr. Dredge speaks, I am not clear as to whether it is Mr. Mottelay, or Mr. Dredge, or myself, that is to be the more astonished at them! How Mr. Dredge comes to think (*a*) that Mr. Mottelay could possibly pirate a work of which he has never seen one line, or (*b*) that I could think so, or (*c*) that the big show at Chicago can possibly patch up the reputation of Messrs. Wiley and Sons in the eyes of lovers of Ruskin's works, are matters at which we may all three be indeed astonished. In my brief conversation with Mr. Mottelay (at which Mr. Dredge was not present) there was small room for inaccuracy. If my memory serves me rightly, we discussed, of Gilbertiana, but three things:—(i) I asked Mr. Mottelay if he could throw any light on the question whether there was, or not, an edition published at Frankfort, as alleged by Ferguson, and which I have never seen or been able to trace. (ii) I drew the attention of Mr. Mottelay to a certain word which is spelled differently in the three known editions of "De Magnete," the meaning of which is a puzzle to scholars. Mr. Mottelay had not noticed this, and could not assist me in the meaning. (iii) I told Mr. Mottelay of a suggestion that had been made as to the significance of the mysterious asterisks in the margin of the folio edition of 1600, which had been thought to constitute a cryptogram, but of which the true meaning was discovered when the preface came to be translated. Mr. Mottelay certainly said nothing to me about inaccuracies in a translation of which only a small part has been done by me, and of which he had not at that date (nor since) seen a single line. As I have said before, I believe Mr. Mottelay to be an honourable man. And now I entirely refuse to believe that Mr. Mottelay would say behind my back what he did not say openly when he met me face to face. What I do not understand is that Mr. Mottelay should not, after our frank and friendly conversation, and the assurance that a place should be reserved for him in the membership of the Gilbert Club, have further communicated with me in the way he had led me to suppose he would do concerning matters in which we both take so great an interest.

Dr. O'Reilly asks me what will be the probable date of publication of the Gilbert Club's English translation of "De Magnete." I can only reply that it is not my fault that the work is not already published. The rough translation was all but complete two years ago, and the members of the Editing Committee who have been working at the revision are all busy men. We are all doing our part as a labour of love, seeking no remuneration for our efforts. The publication of the American translation will not make a grain of difference to us; our work is beyond that stage. Our edition, which is a limited one, is already subscribed for and guaranteed. There will be plenty of room for a cheaper issue to those who are not original subscribers to the memorial edition. My anxiety that the good fame of Gilbert's book shall not be tarnished by the publication of his works in any inferior style is justified by the issue only this year in Berlin of the miserable so-called facsimile photo-reprint of the folio of 1600, and by the ominous circumstance that the American translation is to issue from the publishing house that has so debased the imprint of Ruskin's splendid volumes. Facts are facts, and cannot be disposed of by throwing the epithets "inaccurate" and "abusive" at the man who knows them and states them.—Yours, &c.,

SILVANUS P. THOMPSON.

We have received, too late for insertion, a very long letter from Mr. A. Shippey on this subject. Many of his remarks are answered by Prof. S. P. Thompson's reply. A considerable portion of his letter deals with Mr. Shippey's own family history, his grandfather, resident in Colchester, having owned a copy of "De Magnete." Mr. Shippey appears to be unaware that translations of Gilbert's work have already been published, and that Mr. Mottelay's edition, if published before that of the Gilbert Club, will not be the first version in English.

"I may say," he writes "(although it is not generally known), that it was through my own instrumentality which brought Dr. Gilbert's work to the light of the nation—which historical volume had been buried in the archives of the Royal Institution for years, until it was ferreted out by me in order to compare it with the description of my own volume, which book when brought to me by the librarian was covered with the dust of bygone days; and at the same time he made the remark that 'he did not think it had seen daylight for many, many years.' Hence I feel I have a perfect right to lay claim to the modern discovery of this hidden treasure. . . . ."

LUMINOUS DISCHARGES.

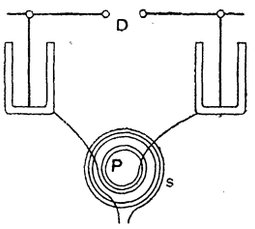
TO THE EDITOR OF THE ELECTRICIAN.

SIR: Since writing my letter which appeared last week, I have been able to obtain experimental proof that the ring discharge in an exhausted bulb undoubtedly acts like a current in respect to its magnetic effects. Two gutta-percha covered wires are wound together so as to form a coil, the two wires forming a primary and a secondary circuit, P and S respectively, each consisting of four turns (*vide* Fig. 6, *The Electrician*, Dec. 9th, page 155. Reproduced on opposite page).

A pair of Leyden jars, with a spark gap, D, discharge through P, and S is connected to a third coil T, also composed of four

Hosted by Google

turns of gutta-percha wire. In T an exhausted bulb A is placed, and inside P and S another bulb B. The spark gap can be so adjusted that the bulb A is either not lighted at all, or only a faint ring-shaped discharge appears in it. On removing bulb B the ring discharge in A will at once become *brilliant*, to be again rendered faint or invisible on replacing B. This can be repeated over and over again. (It is not necessary to perform this experiment in the dark as the discharges are plainly visible in full gaslight or even in daylight.) This shows that the ring discharge in B acts in the same manner as the current induced in a metal ring, which will give the same effect if used instead of bulb B, viz.: it diminishes the mutual induction between P and S.



With regard to the experiment described in last week's *Electrician* by Dr. Jones, might not the effect of allowing the contact breaker to work be that the condenser is sometimes in *series* with the primary, reducing its impedence, and allowing a larger current to flow through it, as described in Dr. Fleming's "Alternate Current Transformer," Vol. II., page 51? At all events it would be interesting to try the effect under the same conditions when the contacts of the break were separated by a piece of ebonite or other insulator.—Yours, &c. E. C. Rimington.

The Park, Norwood, S.E.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I was much interested in your editorial remarks on above, and in Mr. Rimington's letter on the same subject in last week's issue.

In a Paper on the nature of the electric current, read by myself about a year ago, before the Telegraphists' Electrical Society, I gave an explanation of the phenomenon somewhat similar to that given by Mr. Rimington. It was supposed at the time the experiments were first performed that the effect could not be an electrostatic one, because an envelope of wet blotting paper round the bulb failed to screen it off to any appreciable extent. With all respect to the opinion of Prof. J. J. Thomson on this point, I should like to point out that this badly conducting envelope in this case would probably screen off just as little of the electrostatic as of the magnetic action, for two reasons. The first is that if the electrostatic strain is produced during and by the process of formation of the magnetic field, it is produced just as readily inside the envelope as outside. Again, a badly conducting envelope will only effectually screen off a steady or slowly changing electrostatic field, and in this particular case the field is a rapidly—probably a very rapidly—varying one.

For my own part I regard the *electrostatic* as the generator of the *magnetic* field, at least as far as the dielectric inside the helix is concerned. The electrostatic field coexistent with a helical current, I have endeavoured to show, consists of closed rings of lines of induction or strain, which have a radial motion towards the axis of the helix, thus conforming to the law whereby a magnetic field during formation produces an electrostatic strain at right angles to the lines of force, and to the direction of propagation, which again is at right angles to the lines of static induction.

We are not accustomed to regarding lines of induction as existing in a dielectric, except they be attached to two definite points, that is, they have two ends; but there is no reason why they should not form closed rings, although, of course, it is only for a very small space of time that they can maintain themselves as such.

I feel every confidence in predicting that were an insulated or uninsulated straight conductor passed through the middle of a large vacuum tube, and a sufficiently strong Leyden jar discharge passed through it, the luminous effect produced (assuming the return wire to be at a sufficiently great distance) would be a glow round the conductor, most intense near it, and dying away as the radial distance increased (assuming also that stratification or other effects did not come into play). The effect in a straight tube parallel to a conductor would, of course, be like a segment of the former.—Yours, &c.,

J. E. Taylor.

P.O. Telegraph Instrument Factory, Holloway, N.,
December 26, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Tenders Accepted.—The tender of the Staveley Iron Company has been accepted by the Blackpool Corporation for excavating for, and laying, cast-iron pipes, and making good the streets for the electric light conduits.

———— The tender of Messrs. Goddard, Massey and Warner, of Nottingham, has been accepted for the lighting of the pier and pleasure gardens at Bournemouth by electricity. The Town Council are applying for powers to borrow £4,000 to cover the estimated cost of the work.

Arundel Castle.—In our Trade Notes last week we announced that Messrs. Reed, Blight, and Co. had secured the contract for lighting Arundel Castle for the Duke of Norfolk; this is inaccurate. The contract secured by Messrs. Reed, Blight, and Co. is for the station building, the whole of the electrical work being in the hands of the Brush Electrical Engineering Co.

Partnership Dissolved.—The partnership existing between Messrs. W. H. Allen, R. W. Allen, and Richard Wright, engineers, of York-street Works, Lambeth, S.E., has been dissolved so far as regards Richard Wright. Debts will be paid and received by Messrs. W. H. and R. W. Allen, who continue the business under the old name.

Personal.—Mr. A. Grundy is joining Messrs. Baily and Grundy, of Paddington, as manager of the electrical and contract department from the commencement of the new year.

The Pilsen Electric Company.—This Company have recently been incorporated in the engineering business of Messrs. Gwynne and Co., at their new premises in Brook-street Fetter-lane, London, E.C. Under the transfer arrangements, Messrs. Gwynne and Co. acquire the whole business, patent, and other rights of the Pilsen Company. Mr. Rankin Kennedy is managing the electrical department.

Messrs. King, Mendham and Co.—This firm have recently carried out an extensive installation of the electric light at the large clothing establishment of the "Don" Association at Bristol. The installation includes three 1,000-c.p. arcs. The dynamos are supplied by the Newton Electrical Engineering Company of Taunton.

Key's Electric Company (Limited).—In reference to the voluntary winding up of this Company, a meeting will be held at 8, Old Jewry, E.C., on January 25th, at 4:30.

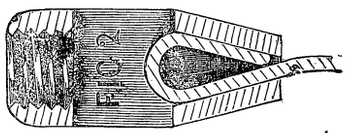
Primary Syndicate (Limited).—It has been resolved to wind up this Syndicate, and Mr. T. D. C. Parker, the secretary, has been appointed liquidator.

The Brush Electrical Engineering Company.—This Company report that during the past year most of the departments of their extensive works have been fully employed, more particularly in the execution of contracts for central station work. Considerable progress has been made with the large station at Bankside for the City of London Company, and the Brush Company are now employed in erecting additional sets of generating plant to enable the City Company to cope with the urgent demands made upon them for the electric light. The strike at Huddersfield somewhat interfered with the work on the large station which the Brush Company have on hand for the Corporation, but this difficulty having been overcome the works are now being rapidly pushed forward. The Brush Company have been successful in securing central station contracts from the Corporations of Worcester and Hanley, for extension of plant at Newcastle, Sheffield, Bournemouth, Chatham and Rochester, Hastings, Exeter, and Shanghai, and amongst the orders for plant for new installations, those at Prescot, Windermere, Killarney, Port Louis, and several towns on the Conti-

Hosted by Google

nent and in the Colonies, may be mentioned. Arc lighting plants have been supplied to Dublin and Glasgow, and the Hanley contract includes arc lights. Exhibition lighting contracts include the Douglas Exhibition and the whole of the electrical plant used at the International Horticultural Exhibition at Earl's Court. With such extensive facilities for supplying large demands, it is not surprising to learn that a great number of isolated installation plants have been supplied by the Brush Company, and these include Arundel Castle and a long list of private mansions throughout the country. The Princess-street Station of the Caledonian Railway, and the Victoria Station of the London, Brighton, and South Coast Company have also been lighted by the Company. Ship lighting plants have been supplied to Her Majesty's ships "Sappho" and "Scylla," to two cruisers built for the Argentine Government, and to a steamer for the Austrian-Lloyd Company. Considerable improvements have been made in the construction of train-lighting plant, with the result that orders have been received for new machines for train lighting on the London, Brighton, and South Coast system, the Adelaide Government railways, &c. A number of important electric traction and power transmission contracts have been secured by the Company, both in this country and abroad. In only one department has the general depression in trade been felt—the rolling stock department; but, notwithstanding this depression, several important contracts for locomotives and rolling stock have come in, including that required for the new Beira Railway, and for the railway at Bangkok, Siam. The Brush Company have been successful in establishing during the past year in the New South Wales Courts the validity of the Edison patent for incandescent lamps, of which, as our readers are aware, the Company are the owners for the Australian Colonies, India, the Cape of Good Hope, and Natal In closing this brief *résumé* of the year's work of the Company, we may refer to the serious loss sustained by the death of the Chairman, the late Duke of Marlborough, whose activity in all matters affecting the welfare of the Company was well known.

THE "LEWIS" LINK.—This a simple device for connecting the top rod of a lightning conductor to a copper strip. It reduces the number of parts, a great desideratum, and ensures thereby a direct continuity. The Link is the invention of, and is manufactured by, Mr. Joseph Lewis, of Great Winchester-street, E.C.



THE SECTIONAL STANDARDS (LIMITED).—In our issue of October 28th last we illustrated the posts used for lighting the streets of Oxford. These posts were designed at Munich, in Germany, and we expressed our surprise in the article referred to that it was necessary to go to Germany for such designs. The Sectional Standards (Limited) is a company which has been established to supply, amongst other manufactures, electric lighting posts, and from advanced sheets of a catalogue now in preparation we find that some exceptionally well-designed examples of this class of work will shortly be placed on the market. The specimens illustrated are of both the useful and the ornamental type. These standards are manufactured in England, and can be supplied in sections of any length. They are suitable for electric lighting posts, brackets, &c., telegraph poles, and similar requirements. As these goods can be shipped in sections as raw material, a considerable demand should arise from the colonies and other parts of the world where public lighting is contemplated.

FIRE.—A serious fire broke out on Sunday last at the Cadby Hall Works of Woodhouse and Rawson United (Limited), through the over-heating of a drying stove. In spite of the efforts of the firemen, the ground floor was completely burnt out, and the remainder of a large building of two floors, 100ft. by 40ft., very severely damaged.

THE REFUSE DISPOSAL COMPANY.—We have received from this Company a pamphlet on "Steam Power from House Dust, for Electric Lighting and other Purposes." By means of a patented system of sifting and sorting of house refuse, the waste paper, rags, iron, broken glass, bones, bottles, and large pieces of coal and coke are separated and are sold or utilised for paper making; while the ashes, breeze and "dust" are used in destructors for raising steam. The table published in *The Electrician* of July 8th, 1892, showing the coal consumption of the various electric supply companies in London, is quoted, and numerous calculations and estimates are given, showing the economic features of the system. It has been recognised by those who have given attention to refuse destructors that some system of storage is necessary where steam is only wanted for a few hours a day, since the destructors can only be used with convenience on regular work.

COST OF THE ELECTRIC LIGHT.—The *Newcastle Leader* of the 22nd contained an article dealing with the cost of electric lighting, more particularly in reference to the favoured coal district of Newcastle.

CALENDARS FOR 1893.—Useful hanging pad calendars are to hand from the Remington Standard Typewriter Company, and from the Indo-European Telegraph Company, the latter showing the tariffs over the Indo Company's system, including the revised rates to Australia.——The E.P.S. Company sends us their pad blotter, which, in addition to other useful features, contains illustrated printed particulars of the Company's specialities, a diary, and a letter index.——A useful pad calendar also reaches us from Messrs. Fletcher, Russell and Co. (Limited), of Warrington. ——The Brush Electrical Engineering Company send us a handsomely-bound waistcoat-pocket diary.

SOCIAL.—The *employés* of the Oxford Electric Company were entertained at a dinner at the works on Christmas Eve, Mr. George Offor, the general manager and secretary, presiding.

BATAVIA EXHIBITION, 1893.—Messrs. Henry Hemans and Co., of Queen Victoria-street, E.C., notify us that as British agents to the above Exhibition, they have opened an office in Kalibesar, Batavia, for promoting the interests of the British section.

BLACKROCK.—The Township Commissioners have had under discussion the question of petitioning Parliament in favour of the Dublin Southern Districts Tramway Bill, which is to come before Parliament at the next Session. It is a Bill to authorise the Tramway Company to improve their tram lines and to introduce electricity as a motive power. The matter has been shelved pending the calling of a special committee.

BOURNEMOUTH.—The Lighting Committee reported that they had considered the surveyor's report upon his examination of the various schemes and tenders submitted in competition for the lighting of the pier and gardens by electricity As stated above, the scheme and tender of Messrs. Goddard, Massey, and Warner, of Nottingham, has been accepted for the lighting of the pier and gardens by electricity. The Lighting Committee further recommended that Messrs. Goddard, Massey, and Co. be asked to submit an additional tender for providing 3,000 1-c.p. lamps for illuminating purposes and for laying on the light to the fountains to be constructed in the gardens, and the Committee's recommendation was adopted, the Chairman of the Lighting Committee (Councillor Moore) remarking that the Committee considered the surveyor's report a very clever and exhaustive one, and that if carried out they would get a very satisfactory lighting of the gardens and pier.

CARDIFF.—The agreement between Mr. W. H. Massey, the consulting electrical engineer, and the Cardiff Corporation, was settled at the last meeting of the Gas Works and Electric Lighting Committee, and Mr. W. Harpur, the Borough engineer, submitted the drawings of the electric lighting station. Mr. Massey's estimate of the total cost of the station and buildings is £32,500, which would, however, leave provision for a larger number of lights than would be immediately required. The estimates were approved and forwarded to the Local Government Board for their sanction, immediately upon receipt of which tenders will be advertised for.

DORKING.—Mr. J. Torr Todman has just completed an extensive electric lighting installation at the large timber works of Messrs. Taylor and Brooker, of Dorking, including nine "Solar" arc lamps, two of 2,000 and six of 1,000 c.p., and a number of incandescence Babcock-Wilcox's boilers are used.

EDINBURGH.—The deputation appointed by the Town Council to inspect and obtain information regarding electric lighting matters from the chief English centres have completed their visit, and have, in association with Mr. Murray, electrical engineer, of Biggar, N.B., compiled a set of questions to which the engineers and managers of the various central stations visited have supplied the answers, and from this document a report will be drawn, and presented to the present Corporation shortly.

FALMOUTH.—The Lighting Committee have suggested improvements in the lighting of various parts of Falmouth, and they have under consideration the question of electric lighting for the Borough.

IPSWICH.—The Corporation is very generally blamed for its action in the matter of the electric lighting powers granted to two companies in the town, with the result that Ipswich is now without the benefit of the electric light, which for a considerable period has been the illuminant of its principal streets. We understand the Corporation, through the Paving and Lighting Committee, have decided not to take up their Provisional Order. It is probable, therefore, that another opportunity will be given to private enterprise to supply the town with a much-needed commodity.

KINGSTOWN.—The Board of Works are about to erect an electric operative room on the east pier, Kingstown; the frontage to be on the lower walk.

LLANDUDNO.—At the last meeting of the Improvement Commissioners a letter was read from Mr. Kingsland on behalf of a Syndicate, for permission to construct an electric tramway along the parade connecting the Great and Little Orme's Heads. It was decided that the consideration of the subject should be deferred to a future meeting.

Hosted by Google

WINDERMERE.—In reference to the laying of the electric lighting cables by Mr. Fowkes, at a meeting of the Local Board, a resolution has been passed to the effect "that the Board withhold its consent to Mr. Fowkes laying his cables through their district until his agreement with the Company has been submitted to them, and has received their instructions and approval."

PATENT RECORD.

APPLICATIONS FOR PATENTS.

December 5, 1892.

22,261. A. F. HILLS. London. Improvements in electric arc lamps.

22,271. C. W. HAZELTINE. London. Improvements in and connected with carbons for electric arc lamps. [Date applied for under Patents Act, 1883, Sec. 103, May 6, 1892, being date of application in United States.]

22,274. E. W. STREETER. London. A new or improved shade or screen for electric and other lights.

December 6, 1892.

22,585. G. L. ANDERS and W. KOTTGEN. London. An improvement in microphone transmitters.

22,308. E. W. APPLEGATE. London. Improvement in incandescent electric lamps.

22,333. E. HARTMANN. London. Improvements in ammeters and voltmeters.

22,344. W. WALTER and F. R. WILKINS. Birmingham. Improvements in galvanic batteries.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

20,413. BAMBERG. Electrolytic apparatus for making caustic soda, &c.

22,255. SWINTON. Electric telephone transmitters.

22,265. STEPHEN and DAVIS. Telephony and telegraphy.

22,304. THOMPSON. Electric signalling for telegraphic purposes.

1,096. SHIELS. Electric signalling on trains.

1,924. GRIMSTON. Electric switch.

5,654. REIGNIET. Dynamo-electric machines.

COMPANIES' MEETINGS & REPORTS.

Fowler-Waring Cables Company (Limited).

The fourth ordinary general meeting of the Fowler-Waring Cables Company (Limited) was held on Thursday, at the Offices, 32, Victoria-street, Westminster, S.W., Mr. Wm. Fowler (Chairman) presiding.

The SECRETARY (Mr. D. Stephen) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen, it now rests with me to move—

"*That the report and accounts as distributed to the shareholders be received and adopted by this meeting.*"

In doing so I wish to make a few observations with regard to the present position of the Company. Of course we all regret that it is not possible to declare a dividend, but I do not think any of us are surprised, having regard to the fact that the Company is still young and has therefore difficulties which all new companies have to contend with. But I wish to point out the important increase in the business of the Company, and the improvement in its position, since I addressed you about a year ago. During the past year—that is, the year ending September 30, 1892—the increase in the business has been fully 20 per cent., and instead of having a loss on the year's working of £1,500 we have a profit of £480. This may not seem a great change in itself, but it is a very important improvement, as we now show a profit on the working of the year for the first time. But there is more than that to say with reference to our present position. If you take the period from September 30, 1892, to the present day there is an increase in the business, as compared with the same period last year, of more than 100 per cent., which shows clearly, I think, that the business is rapidly developing. The most important point to bring before you to-day is, I consider, the fact that our working capital is insufficient, as has been shown during the year by our having to issue debentures to the extent of £10,000, almost the whole of which have been taken or placed by the Directors. Now, it is important to observe here that probably still more capital may be required as the business develops, and it is perfectly evident that if the shareholders are not disposed to co-operate with the Board by subscribing for new capital, it must be raised at their heavy expense. That is perfectly evident. The Directors are not disposed to allow the Company to be injured by insufficiency of working capital. I may say that we, the Directors, have entire confidence in the future of the Company, if sufficient capital be provided. For real and permanent progress sufficient working capital is indispensable, for, without it, we cannot keep pace with the constant development of our business. That, I think, every man of business will admit. I wish, therefore, to impress upon the shareholders the urgency of co-operating with the Directors, when the time comes, in providing the requisite additional capital. I may observe that one reason why we do not show more immediate profit is, that we have to provide larger plant than the current business may require, because we must be prepared to execute large orders speedily and well at any time. I wish also to say that I have never seen since this Company was founded—and I think I may claim to have been a diligent Director—such a list of inquiries and probable orders as we have before us at the present time. That, I believe, will be regarded as a very satisfactory feature, and one that ought to help the shareholders in forming their opinion as to the future of the Company, and the desirability of contributing towards the raising of further capital. I really think this is substantially all I have to say. I regret to see that we are to-day almost entirely a body of Directors turned into a committee for the purpose of forming a general meeting, but what I have said will, I hope, be read by other shareholders, and I trust it will appear satisfactory to them, as I think it does to us. Perhaps someone will be kind enough to second the motion for the adoption of the report.

The Lord MEDWAY seconded the motion.

Mr. SEON said it was a considerable surprise to him that there was to be no dividend. He had invested £700 in the Company, and when he did so he had no idea he should have to wait three or four years for any return. Perhaps the Chairman would say when he thought there was any reasonable expectation of the shareholders getting a dividend.

The CHAIRMAN: Well, gentlemen, I cannot assume the functions of a prophet at this moment, but I really believe—although I do not wish to pledge myself absolutely, or the Board either, for I have no authority to do so—that if we go on during the present year as we have begun it, we shall see something in the way of a dividend next year. With regard to what the shareholder has said about his holding, I may say that I have a great deal more in the Company myself than he has, and as I have never yet received a sixpence in fees or dividends, I am exactly in the same position as he is. I regret there being no dividend as much as he does, and more, because I feel the responsibilities of a Director. I am extremely sorry at the way things have turned out. When this Company was formed, a very intelligent friend of mine—who, I am sorry to say, is now dead—said to me: "You have an excellent Board, and very good prospects; but you won't make any money for three years." I said to him: "You are an encouraging person, certainly." And he replied, "Well, that is my experience. I have had a large experience of telephony, and I find it takes a long time to make money in this kind of business." That has been our experience. We have worked against great difficulties, but I believe we are now surmounting them. Promises I cannot make; I can only express my hope and belief that we are now on the point of paying dividends, and I think the fact that we show a profit for the past year, although small is, at any rate, encouraging (Hear, hear).

Col. WYNDHAM MURRAY, M.P., remarked that it was foreshadowed at the last meeting that there would be a dividend to divide this year. As that statement had not been carried out, he thought it would be an advantage if the Chairman could say upon what grounds he based his anticipation. He did not wish to impute blame to anyone in the matter. He also wished to draw attention to the fact that when he bought his shares it was stated that the Company had been realising 24 per cent. upon its capital, and that there was a possibility and probability of an increase in the percentage. He thought that was a point which required some explanation.

The CHAIRMAN: I have just looked at what I said last year, and undoubtedly it is true that I did then anticipate our being able to pay a dividend this year, and I am just as much disappointed as anyone else that we are not able to do so. There have been great difficulties to contend with, one of which must be obvious to anyone, namely—that the fixed expenses in a business like this at the commencement are always very large in proportion to the business done. You cannot keep them down beyond a certain point, and at the same time ensure efficiency. That has been our experience, and we did not have the amount of business up to September 30, 1892, that we anticipated last year. We have done our best, and we have had excellent management, which is everything. I never felt more satisfied with the management of the business than now. I greatly fear holding out anticipations for the coming year, because, as has been seen to-day, if I say a word of hope which is not realised, I shall be found fault with. At the same time, I must say that I feel we are in a better position—a great deal better—than we were in a year ago. I cannot prophesy what will be the fruits of the current year, because I am unable to tell what fluctuations may arise. With regard to the statement in the prospectus alluded to, it must be borne in mind that that statement was perfectly true, as far as the capital then involved in the business was concerned. There can be no question about that, and it would not surprise me in the least if similar results are obtained in years to come; but it is a different thing to pay interest on a small capital like that in the business at that time than on the larger capital which we now have. One of my colleagues just reminds me that if you look at the share list you will find a large proportion of the shares is held by the Directors and their friends, so that our interests and yours are identical. This is not a concern in which the Directors are making money at the expense of the shareholders; in fact, we are in a worse position than the shareholders, because, for all our trouble and labour in connection with the Company, we receive no reward. But we have worked in your interest and our own, and I hope and believe we shall succeed.

The motion was then agreed to unanimously.

The CHAIRMAN then moved:—

"*That the appointment of Mr. Geo. F. Smart as a Director, Col. J. T. North and Mr. R. S. Waring having resigned their seats at the Board, be confirmed.*"

Hosted by Google

Mr. GEORGE FLEMING seconded the proposition, which was carried.

Mr. WALTER CHAMBERLAIN proposed the re-election of the retiring Directors—Mr. William Fowler and Mr. George Fleming.

Mr. R. W. EDDISON seconded, and it was unanimously approved.

On the motion of Mr. Leon, seconded by Mr. George Fleming, the retiring auditors, Messrs. Cooper, Brothers, and Co., were re-appointed.

The proceedings then terminated.

The following is the report above referred to :—

The Directors announce that there has been again an increase in the volume of business done, as compared with the previous twelve months, with the result that this year a small profit has been earned. The business is steadily growing, and the Directors believe will show continuous development with increasing profits as time goes on, more especially because a larger turnover reduces the average charge for general expenses, an item which is always disproportionately heavy in a new business ; meanwhile, good orders in different departments have continued to come in since September 30th.

The actual capital of the Company has, unfortunately, proved insufficient for its requirements, and the Board therefore, in May last, authorised an issue of Debentures to the amount of £10,000. Of this sum, £5,500 has been taken up, chiefly by the Directors themselves, after full opportunity of subscribing was given to each shareholder. This amount has sufficed for the present, but the employment of a still larger working capital will be necessary before any considerable development of the business can be suitably met. The Directors believe that such an increase would be justified by the results

Colonel J. T. North and Mr. R. S. Waring having ceased to be Directors, Mr. Geo. F. Smart has been chosen to fill one of the vacancies thus occasioned. The retiring Directors, Mr. William Fowler and Mr. George Fleming, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., offer themselves for re-election.

Mr. A. E. MAYOR, the General Manager of the Company, reports :—

"In reviewing the progress of the Company for the past year it is satisfactory to note an increase in the volume of business. The electrical industry, however, has not escaped the prevailing depression, and our turnover has not yet reached a figure which would fully employ the resources of the works and staff. A brief *résumé* of the principal work completed during the year will sufficiently indicate the extent of the Company's operations, and the direction in which further developments may be confidently anticipated. In my last report I referred to our contract for mains with the London Electric Supply Corporation—this has been extended, and we are still delivering large quantities of high tension concentric conductors for their system in London. We secured the contract for, and have now completed, the extensive underground electric light system at Exeter, and have at present a similar contract at Brighton. A number of Irish towns have been cabled on our system, and we are carrying out the contract for the electric light mains of a large town in Sweden. Negotiations are well advanced for similar contracts in this country. In general electric lighting work our manufactures have met with increasing favour, and have been in several instances specified for specially difficult conditions, to the exclusion of other systems.

"In telegraphy, the railway companies continue to employ our various types of telegraph cables, and we have now in hand a contract with the Secretary of State for India. This has been placed with our Company after prolonged tests and experiments by the officers of the Government in India, who have satisfied themselves as to the high value of our insulating material in resisting the deteriorating effects of the heat and moisture of the Indian climate. We are justified in expecting that this contract will be followed by the further application of our cables for electrical work in hot climates where permanent efficiency cannot be secured with rubber or gutta-percha.

"Recent enterprise in telephony has stimulated the manufacturers to special exertions in the production of cables suitable for the transmission of telephonic currents over long distances, and notable advances in this direction have been made within the last few years. Since the organisation of the Company's factory at North Woolwich, this important work has been the subject of constant experiment and investigation, and we are now manufacturing long-distance telephone cables of the highest efficiency. It is satisfactory that the resources of our works, and the perfection of the machinery and appliances, have enabled us to undertake, and successfully to complete, large contracts both in this country and abroad for the new type of cable.

"Notwithstanding the preliminary difficulties which always beset a new industrial undertaking, and the exceptionally keen competition which we have had to meet from the beginning of our business, the constantly growing demand in every branch of electrical engineering, and the high favour with which our manufactures have been received, foreshadow the early success of the Company."

Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

The third annual ordinary general meeting of the shareholders of this Company was held on the 23rd inst. at the City Terminus Hotel, under the presidency of Mr. J. Jepson Atkinson.

The SECRETARY (Mr. J. Shurmer) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, at the outset of my remarks I would like to remind you that ours is a syndicate company, formed not for carrying on industrial operations, but for the sale of our patents in foreign countries, and that the value of our assets therefore largely depends on the success of the subsidiary Companies so formed. I need hardly remind you that in the three years of the Company's existence we have met with no little success, inasmuch as we have disposed of several of our most important patents, and have paid back in dividends the whole of our priority share capital. The accounts which are before the meeting are plain, and do not require much explanation, except, perhaps, a word in regard to the market value of our assets. At the end of last year the value of these assets was considerably higher than it is at the present moment, but it is in accordance with the usual practice to show such investments at cost price in the balance-sheet, whether they be at a discount or at a premium. I am convinced that in the course of the coming year the market value of these assets will very materially improve. It is the intention of the Board to have the accounts for 1892 prepared immediately upon the expiration of the present year, and to meet the shareholders with the same not later than February next. The year 1891, which is now under consideration, did not see the formation of any new Elmore Companies, and the year, as mentioned in the report, has been one of establishment and development of existing Elmore factories. I feel exceedingly loath to venture upon prophecy or more promises in regard to the position and prospects of this or of any of the Elmore Companies, but, Gentlemen, I cannot refrain from assuring you most emphatically and deliberately, after further close and personal experience of the working of the Companies since we last met you, that notwithstanding the seeming failures and the many disappointments that have beset our path, yet the coming year will be one of substantial prosperity to the manufacturing Companies from a shareholder's point of view. We have to admit that we have, no doubt, been too sanguine in respect to the length of time required to overcome the difficulties of starting and developing a new business, aggravated as they have been in one case by the smallness of the working capital available ; but these difficulties are now removed and the Elmore process to-day is perfectly successful on a commercial scale, and I am certain that as a consequence our own assets will considerably improve, and as a further consequence we shall be able to dispose of other of our unsold patents. We have refrained from alluding in our report to the new operations of the Company during the present year, as it is our intention, as I have already said, to meet you again very shortly ; but I may here say that we have during the present year had to very largely assist the French Elmore Company financially, our advances to them being secured by mortgage at interest. The wisdom of this policy cannot be better seen than by looking at the undoubted success which that Company has now achieved at its Works, and which could not have been achieved but for the assistance we have rendered them, and thereby we have secured an established value to our very large stake in the French Elmore Company in the shape of shares and debentures, which would certainly have been practically wiped out had any financial disaster occurred to the French Company. Not only so, but in helping to make the French Company a commercial success we have also been doing good service to the other Elmore Companies. It would have been a great pleasure to the Directors to have found themselves again in the position of declaring a dividend of 100 per cent. to the priority shareholders, but, as stated in the report, we hope to be able to do this in the course of 1893 ; and if you ask me on what grounds I think it is possible, I reply that I honestly believe and know that the Elmore process is perfectly successful, and that, consequently, with proper management, the Companies themselves will be successful, thus enabling us to realise our investments for considerable sums in cash, and at the same time enabling us to dispose of other of our patents. Only this week we had a firm offer of a substantial sum in cash down for our ordinary shares in the French Company. This we have declined, as we do not consider it good enough, in view of the assured financial and industrial position which the French Company now really occupies, and it was to give that Company time to attain to this position that we have reluctantly deferred our meeting until so late in the year. As before stated, however, we intend to publish the 1892 accounts within the next few weeks, and now that the funds required by the French Elmore Company have been arranged for, I have every reason to believe that between now and our meeting in February next the value of our investments, as shown in the balance-sheet, will have considerably improved above the price at which they stand to-day. We shall be happy to answer any inquiries from the shareholders. I will now propose :—

"*That the accounts and report, as submitted to this meeting, be received and adopted.*"

Mr. JOHN MACFARLAN seconded the motion.

General FIFE inquired what quantity of finished work the French Company now put out per week.

Mr. INVERARITY said he would propose as an amendment :—

"*That the report and accounts be not passed.*"

He did not, he said, propose the amendment in any captious spirit, but in order that the rights and privileges of the priority shareholders should be defined and laid down at that meeting. He regretted very much to see that those rights and privileges had been seriously invaded, if not damaged, by the Directors in making large loans to the French and German Companies.

The SECRETARY stated that nothing had been lent to the German Company by the Company.

Mr. INVERARITY said he believed that £5,000 had been lent to the French Company, and, in addition to this, £50,000 was last year and the year before lent to the French Company, which, he believed, had not all been realised. He maintained that these advances to the French Company were illegal, and beyond the power of the Directors to make. Clause 110 of the Articles of Association said that the priority shareholders should be entitled to all profits up to 100 per cent., and there were no reservations to that. This laid down for the priority shareholders

Hosted by Google

clear privilege. Another clause stated that "the rights and privileges of the shareholders shall not be affected or dealt with except under an extraordinary resolution passed at a general meeting." No such meeting had been called, and no such resolution had been passed by the shareholders. The money had, therefore, been lent by the Directors on their own responsibility, and, therefore, he maintained that such loans were absolutely illegal. What he desired to know was, how far it was intended to go in this direction. They might be asked to assist in a similar way other companies. Ten per cent. interest had also been guaranteed by the Directors on £200,000 of preference shares in the French Company, and the interest was guaranteed out of this Company's profits, and without the shareholders' consent. He warned the Directors that he held them individually and collectively responsible for any loss he might sustain. The Directors ought to have called the shareholders together, under Article 6, and have asked them for power to lend money to the French Company, when, no doubt, they would have given the requisite authority. Then, he did not grudge the Directors their fees, but, under the 54th clause of the Articles of Association, it was stated that the remuneration of the Directors should be settled at that meeting. The remuneration charged in the accounts had not been settled at the metting, and this matter was also illegal.

After a few remarks from Mr. Nias and Lieut. Philips,

The SOLICITOR stated that the 22nd Clause of the Memorandum of Association was as follows :—"To lend money to such persons and on such terms as may seem expedient, and in particular to customers of, and persons having dealings with, the Company, and to guarantee the performance of contracts by members of, or persons having dealings with, the Company," and so on. Then, with regard to the question of the Directors' remuneration, Clause 72 laid down that the Directors were entitled to take up to £1,500 a year. Both those acts were, therefore, legal ; but he desired them to understand that he said nothing whatever as to whether they were judicious or injudicious. The Memorandum of Association, he reminded them, overrode the Articles.

Mr. FREDERICK L. RAWSON (a Director) observed that the real point in regard to the assistance which had been rendered to the French Company was not a question of law, but of expediency; but if the Directors had acted wrongly they must be held responsible.

Mr. SIMPSON stated that on the debit side of the accounts there appeared to the credit of the Company £9,000, as investments given as security for a loan to the French Elmore Company, and the entry added "as *per contra*." There was no debit, practically, at that time at all against this, and if the Directors had parted with these securities, why did they give themselves credit for them among the assets? Then, comparing 1891 with 1890, there was a "leakage" of about £30,000 in the value of the French and German securities held. In 1890, too, they had cash at the bankers' amounting to £37,691, whereas in the balance-sheet now presented to them, up to December 31, 1891, there was the remarkably small sum of £726. He wanted to know what had become of the difference, for he could see nothing in the accounts to show where it had gone to. The certificate of the auditors did not certify that the accounts were correct, but merely that they tallied with the Company's books ; and the certificate was dated the 5th of April last. Why, therefore, were not the accounts presented to them until eight months later? The securities were valued at eight times their market value. He regarded the balance-sheet as erroneous with respect to the points he had mentioned, and he considered it a farcical document as any practical guide to the position of the Company. He seconded the amendment.

Mr. SWEETING inquired the amount which had been received from the sale of the American patents, and the amount to be received.

A SHAREHOLDER asked for an explanation of there being only four Directors mentioned on the present report compared with eight at their last meeting, He also spoke of the dwindling down of the assets.

Mr. F. L. RAWSON, in reply, at the request of the Chairman, said he desired first to deal with the main policy of the Company, as that was really the pith of the whole matter. If the Directors had done anything wrong, it was in respect to the main policy of the Company. He, therefore, desired to put before them the position they were in at the end of last year and during the beginning of this year, because that was when the policy was determined. At that time they were all in great expectation. There had been a meeting of the English Elmore Company, when they understood that the works were turning out large amounts, and were about to turn out still larger amounts and to pay big dividends. At the time in question they were all "expecting to become millionaires in a very short time." He had not been able to be present at the beginning of their meeting, but he supposed that the Chairman had informed them that, with respect to the actual Elmore process, they had not been mistaken, and that where they had all been wrong was in regard to the general organisation of the Elmore business, which had not at all been satisfactory. Their own Company at the time in question were in this position: that they held a large amount of securities ; in fact, nearly all their assets consisted of shares in the different Elmore Companies, the remainder of their assets being patents for working the Elmore process in various countries. Patents were things which could be sold if things went all right, but if they went wrong they could not be sold ; and patents were of no use unless they had money to work them. At the time referred to they found that the French Elmore Company—it was of no use disguising the matter—were very "hard up," and the question was whether that Company was going to fail or not. In his opinion, speaking as an expert, if the French Company had failed, he believed the whole of the Companies would have failed. He spoke as an expert with a thorough knowledge of the subject, and he did not believe that there would have been an Elmore Company alive at the present time if the French Company had failed. They must remember that the English Company had not only at that time not borne out the statements it had made, but had nothing like borne them out. All the Elmore Companies were "hard up" at that time, except their Company, which had a certain amount of money. The French Company came to them and said, "We are going to fail unless you lend us some money." As the shareholders might imagine, they led to long and anxious consultations among the Directors at the beginning of the year, and, so far as he was concerned, he found himself in one of the most difficult positions he had ever been in. The question was, how were they going to pull the French Company through while that Company was getting over their initial difficulties? He discussed the matter with nearly all the large shareholders, and eventually the conclusion come to was that the best thing would be to lend the French Company a certain amount of money, taking the security they had, which was a second charge on the property after the £50,000 of debentures. The decision was arrived at with considerable anxiety, because he knew that if the matter went wrong he would be generally condemned, and that if it went right no one would thank him. He advised the Board technically, telling them, "If you do not find the money there will be a smash all round, and your position as the Foreign Elmore Company is that you may be able to distribute a small amount of money on your priority shares. I also advise you that if you find this money the French Company may be able to get enough money to pull the thing through." The Directors cross-questioned him as to his opinion, and he gave them facts and figures. They afterwards lent the money to the French Company, which was saved, and then the question arose, how were the French Company to get the rest of their money. He believed that at the beginning of this year the French Company had to get £90,000, and this seemed a Herculean task. What took place was this, that the French Company borrowed a certain amount from this Company on a second mortgage, and this Company helped them by lending them securities, the French Company becoming debtors to them. They lent securities to the French Company on which the latter could borrow money, whereas they could not borrow on their own credit. If it had not been for a mistake which the French Company made at the beginning of January, this Company would have got their money back ; but the French Company made the fatal mistake of letting people know their financial position. One of the shareholders had asked why the Directors had not called a meeting of the shareholders to get authority from the latter to lend the money to the French Company, but if they had done this they would have made the same mistake which he thought the French Company had made, in allowing people to know what their financial position was. The sole reason why the Elmore shares went to the high prices they were once quoted at was because people believed so strongly in the Elmore process. He himself bought 1,000 Elmore shares at $8\frac{1}{8}$ and 1,000 at $7\frac{1}{8}$—not as a speculation, but in the belief, which he shared with the other Directors and their friends, that they would make a fortune out of it, as they imagined that they had such a good thing. The fact was that they had made a mistake in not allowing sufficient time in their calculations for the development of the thing, but had been under the impression that everything would be all right in six months or nine months. As he had said, the French Company made a fatal mistake in letting their financial position be known. Their shares were at $2\frac{1}{2}$ $\frac{3}{4}$, but within twenty-four hours they fell to under 2, when it was "good-bye" for the chances of that Company getting the money they required, which he believed they could otherwise have obtained. This Company held £60,000 in the shares of the French Company, as well as debentures ; and why they helped the French Company was that, in his opinion, it was the only company at the time that could save them, the English Company being so slow in getting to work. If there had been a smash-up at the time, this Company could not have sold their patents, and the shares which they held would have been worthless. He thought, therefore, that they would probably agree with him when he said that, under the circumstances, they had done right in assisting the French Company by lending them money. They took legal advice on the proceeding, and they were told that if they genuinely believed they were going to pull the French Company through they would be acting rightly in assisting that Company, but not otherwise. The secretary reminded him that the amount lent was £35,000. The result of the course taken had been that the French Company had managed to pull through and pay their French creditors ; and he might inform them that the French law was very severe. He was informed that if a creditor were not paid at once an undertaking was sold up immediately. The French Company had paid off practically the whole of their French creditors. They had borrowed a certain amount from other people besides this Company ; and as to the placing of their Debenture stock, which was the real difficulty of the French Company, they had a contract with responsible people, and he was informed they had received £19,000 on account. They could, therefore, consider that the French Company were now through, and that all the difficutly and danger which their own Company had run was over. It did not matter much to them now if the French, or even if the English, Elmore Company smashed, because there were the returns of the French Company's working, which showed a steady out-turn of ten or eleven tons a week. This fact put this Company in an altogether different position in regard to the American and the other patents which they held. They had now people coming to them who were prepared to buy the Russian patents. They had had an offer for the Belgian patents, but they had declined it. They had not given a guarantee on £200,000 of the preference shares of the French Company ; they had limited it to a smaller amount, and on the later preference shares they had given no guarantee. In his opinion the French Company would not have got the £19,000 that he had referred to, unless this Company had given them their guarantee. When they lent the money to the French Company they got a good rate of interest for it as well as a bonus, and the bonus would more than cover anything which they might have to pay under their guarantee. With regard to the question of the Directors' fees he believed that they had taken £1,500. They had a certain amount of interest in the Austrian Company, their shares in which, however, would not become of any value worth mentioning until

Hosted by Google

hat Company made profits, and until the Austrian Company got a sufficient amount of capital to turn out a decent quantity of stuff. He advised the Austrian Board not to endeavour to get their capital until the French Company had emerged from their difficulties, pointing out that the latter Company was the key to the whole position. They would have gathered from what he had said, the reason why the Directors had not called that meeting earlier—namely, that if they had had their meeting, and it became known that the French Company was in the position he had stated, the latter could not have got their capital. The other Directors had resigned their positions on account of personal differences, but one of them had had to leave because of his official position, and another of them, Mr. William Elmore, had resigned because the Directors of the English Company had insisted on his giving all his time to the work of that Company in Leeds.

The CHAIRMAN remarked that Mr. William Elmore resigned his position on the Board of this Company, because he thought it would not be right for him to draw remuneration from the Company while he was away.

Mr. RAWSON observed that that was a very good reason also; but he had been given to understand that the new Directors of the English Company had stated that they would have nothing to do with the Company unless Mr. William Elmore gave his whole time to it. He would be quite contented as an expert to see a regular output of 10 tons a week by the French Company, because he knew that with such an output established it would be no more difficult to turn out 20 tons, or, for that matter, 100 tons. An output of 12½ tons ought to pay expenses, but the works were laid out for turning out 80 tons a week. The French Company gradually increased their output up to 14½ tons a week. They then made arrangements for getting out their debentures, when the whole thing fell through, for the reason he had stated, and for a short time they had not the money to buy the copper to put into the tanks. He had recently seen one of the *employés* of the French Company, who had informed him that directly they got the money they required their out-turn would be 18 tons a week. What the Americans wanted was to see 20 tons a week turned out. As to whether this Company would help other companies in the future. he did not care to take such a responsibility as to lend them money, and he would be glad if the shareholders would take this responsibility off his shoulders. On December 31, 1890, their securities stood at £178,000, and there were sundry creditors £47,000, who had been paid off out of investments which the Company had held. At the date mentioned there were sundry debtors £22,000, securities £178,000, and cash in hand £37,000, making a total of £237,000; but the sundry creditors had been reduced from £47,000 to £5,000, and deducting this £42,000 from the £237,000 the difference was worked out.

Mr. PIXLEY, one of the auditors, explained the question regarding the item in the accounts of £9,000 referred to by Mr. Simpson.

Mr. RAWSON, continuing, stated that the cash they received for the American patent had been lent to the French Company.

A SHAREHOLDER: How much?

Mr. RAWSON: £35,000. That is the total amount we have lent, and we have saved the French Company with it. There is about £200 more to receive.

Mr. INVERARITY inquired whether, if the shareholders passed the accounts, the Directors would agree to lend no more money until the next annual meeting.

Mr. RAWSON said that they certainly would. Was he, however, to understand that the meeting would authorise the Directors to lend their securities, which were paper securities, in order to help the other Companies?

Mr. INVERARITY: No. (Voices: No, no.)

The CHAIRMAN said that he gathered that the amendment was withdrawn. (Voices: No, no.)

Mr. RAWSON: The amendment is a direct negative.

The SOLICITOR: It is not an amendment; it is only voting against the resolution.

The CHAIRMAN then put the resolution which he had proposed to the meeting, when 23 voted for it and 22 against it. There being some misunderstanding, he submitted the motion again, and announced that the numbers in favour of it were 28, and against it 22. He, therefore, declared it carried.

Resolutions were afterwards passed re-electing Mr. F. L. Rawson to his seat at the Board, and re-appointing the auditors.

Oxford Electric Company (Limited).

The annual general meeting of this Company was held at the offices, 45, Broad-street, Oxford, on the 9th inst., Sir Henry Mance presiding. The Company has supplied us with the following particulars:—

Mr. GEORGE OFFOR (General Manager and Secretary) having read the notice of meeting,

The CHAIRMAN explained that no accounts could be presented, as they would have to be made up in accordance with the Act of Parliament to December 31st, after which they would be audited by the Board of Trade and presented to the shareholders as early as possible in the spring. He took the opportunity of congratulating the shareholders upon the satisfactory progress of the Company since the opening of the works on June 18th last, the Corporation, the University, and the citizens generally having supported the Company in a very practical manner, and started them on what promised to be a most prosperous career. A contract for street lighting had been entered into with the Corporation for three years upon profitable terms to the Company; the current had also been introduced into seven of the Colleges, viz., Brasenose, Hertford, University, Trinity, Balliol, St. Mary Hall, and Magdalen. An agreement had been entered into for lighting St. John's College throughout, which would be completed during the Christmas vacation. In addition to the above, the theatre, some of the hotels and banks, and many of the leading commercial establishments had been supplied, the number of places connected with the Company's mains being upwards of 70.

With the election of the auditor, and a vote of thanks to the Chairman, the proceedings terminated.

Edinburgh Electric Supply Corporation (Limited).

The annual meeting of this Corporation was held at 17, St. Andrew-square, Edinburgh, on Friday last, Mr. Walter Berry presiding.

The Managers (Messrs. George Deas and Co., C.A.) submitted the third annual report, which stated that the interest taken in the electric lighting of Edinburgh is daily gaining strength, and there is a strong feeling in favour of supporting a financially strong and locally influential Corporation such as this, which the citizens of Edinburgh have themselves formed. Judging from present appearances, certain portions of this city will be lighted by electricity before this time next year; and the Directors have every reason to hope that this Corporation will be employed by the Town Council to carry out the work.

The CHAIRMAN, in moving the adoption of the report, said that when he addressed them on the occasion of their second annual meeting he said that they were unable to report any progress towards a definite realisation of the object for which the Corporation was formed. He had, to some extent, to repeat the same story that day, but with the satisfactory addition that their fate must very soon be decided; for the Town Council, which had to determine if it would undertake the electric lighting of Edinburgh on its own account, or delegate the authority to others, had recognised that the operations to enable it to comply with the conditions laid down by the Board of Trade must be commenced forthwith. He did not think it probable that the Town Council would undertake the work themselves. They had plenty on hand, and were already overworked. He thought it most probable that they would entrust it to this Company—(1st), because of the local and representative position of their shareholders; (2nd) because of their unquestionable financial power; and (3rd) because their shareholders would be the most important consumers, and would have a paramount interest in seeing that the work was well and substantially done, with as little disturbance to the streets as possible. Their interest and those of the Town Council were in many respects identical. They should, of course, look for a fair return for their capital and risk, but to a certain extent their Company might be considered as co-operative. He had no authority from his co-Directors for giving an opinion, but personally he thought they were entitled to aim at 7 per cent. dividend on their shares. The Directors had never advertised for shareholders, or offered founders' shares or any other inducements, but, nevertheless, applications had come in, and they had now on their list 212 names, subscribing £32,775. The great majority of their shareholders had taken small preliminary holdings with the avowed intention of increasing their interests largely if the business was carried on, and he had no doubt that all the capital which they might choose to issue would be immediately absorbed when they were prepared to offer it. The Directors had met frequently during the year, and had given much attention to new developments in electric lighting both at home and abroad, and they were quite prepared, with the assistance of their consulting and acting engineers, to enter upon negotiations at any moment. He trusted that their patience would be rewarded, and that at their next annual meeting they should not only merit the congratulations of their shareholders, but the acknowledgments of a long-suffering public for thorough work performed. He would only add that they had as many conditional orders for installations promised as justified them in anticipating solid financial success.

Mr. JOHN M. M'CANDLISH seconded the motion. He thought the inhabitants of Edinburgh were getting very impatient on the subject of the introduction of electric lighting. They were behind many smaller towns in this matter. He also thought the public would not view with favour the Corporation taking the electric lighting into their own hands, but would rather see them making suitable terms with a Company such as this. Certainly no other Company had anything like the claim that they had on the Corporation.

The report was adopted, and thanks were given to the Directors for their gratuitous services.

Yorkshire House-to-House Electricity Company (Limited).

The first ordinary general meeting of this Company was held on Wednesday at Leeds, Mr. Grosvenor Talbot presiding.

The report, a copy of which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN, in moving the adoption of the report, pointed out the great amount of work which had been performed by the present Directors. The prospectus was issued on March 26th, and by April 4th all the necessary requirements for the application of a Provisional Order had to be completed. It was, however, done, but only by the great exertions of the Directors, who held almost daily meetings. They obtained the Provisional Order, which gave them power to light with electric light the whole of the borough of Leeds. So far as he was able to ascertain, he was informed that they were not likely to be interfered with so long as they supplied a proper light. They had purchased a site in Aire-street which possessed very many advantages, one of these being that they were immediately adjoining their lighting area. The question of material was a very important one for them, and so far as this was concerned they had obtained very great advantages. They could obtain water from the river Aire, which only required filtering. They obtained this for nothing. By purchasing this site they had also dispensed with the cost of a central

Hosted by Google

town office. Then they could have coal brought up to their works on the canal. They had 109 shareholders in the Company, who had taken up 7,298 shares. The capital which they possessed was quite sufficient to carry out the installation. Then came the question of system, and he was pleased to say that the system suggested by Mr. Hammond, their engineer, and which was working successfully in other parts of the country, had been adopted. This system, he was pleased to say, had been inspected by Mr. W. H. Preece, who had expressed his approval of it. All the plant was now manufactured, and ready for laying down at the works. Up to the present time they had applications for the installation of 8,000 8-c.p. lamps. When the works got fully going he had no doubt that they would have as many lamps to light as they could supply. The cables had not yet been laid all over the borough, but only the Headingley portion remained to be completed, and this could be done in a very short time. If it was possible for a company to make the supply of electricity pay, they would do so.

Mr. R. W. EDDISON briefly seconded the resolution.

Mr. R. W. HAMMOND, in supporting, pointed out the many advantages to be derived from the electric light, especially by shopkeepers. He intimated that the Leeds Corporation had power to purchase the works when they thought proper.

The resolution was carried unanimously.

Mr. Grosvenor Talbot and Mr. Robert W. Eddison, retiring Directors, were re-elected, and the proceedings terminated.

The General Electric Power and Traction Company (Limited).

The second general meeting of this Company was held at Winchester House, Old Broad-street, yesterday. The notice calling the meeting stated that:—

"Owing to the protracted illness of the Secretary, the accounts cannot be got ready in time for the meeting, but the above meeting will be adjourned until an early date in January, when the accounts will be submitted. The business will be purely formal."

The meeting was held *pro formâ*, and adjourned to January 31, next, without discussion.

NEW COMPANIES, STATUTORY RETURNS, &c.

AFRICAN TRANS CONTINENTAL TELEGRAPH COMPANY (LIMITED).—This Company was registered on December 27th, with a capital of £140,000, in £1 shares, by Hollams, Sons, Coward and Hawksley, solicitors to the Company, Mincing-lane, London, E.C. The objects are to construct or procure the construction of telegraphs anywhere on the Continent of Africa; to construct or procure the construction of any other telegraphs in connection therewith, or which may seem, directly or indirectly, calculated to feed or develop the Company's telegraphs in Africa or elsewhere; to carry on the business of a telegraph, telephone, and electric light, heat and motive power supply company; in particular, to establish, work, manage, control and regulate telegraph and telephone exchanges and works for the supply of electric light, heat and motive power; to transmit and facilitate the transmission of telegraphic and telephonic communications and messages; to undertake the supply of electric heat or motive power for public or private purposes; to carry on any other business, calculated directly or indirectly to increase the value of the Company's property or connected in any way with electricity; to construct, lay down, carry out, work, sell, let on hire, and deal in telegraphs and telephones and all kinds of works, machinery, apparatus, conveniences and things capable of being used in connection with any of the foregoing objects, and in particular, cables, wires, lines, stations, exchanges, reservoirs, accumulators, lamps, meters, and engines, and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity and the transmission of telegraphic and telephonic messages. The subscribers are:—

Registered without Articles of Association.

AUTOMATIC GEM AND GOLD SEPARATOR SYNDICATE (LIMITED).—This Company has been registered with a capital of £1,000, in 1s. shares, to acquire, develop, and turn to account certain inventions of W. S. Lockhart, of 67, Granville-park, Blackheath, S.E. (who is appointed managing Director), relating to the separation of gold, and gems from other substances by means of electricity or otherwise.

BRISTOL AND KINGSWOOD ENGINEERING AND BOILER COMPANY (LIMITED).—Thi Company has been registered with a capital of £15,000, in £1 shares, to carry on the business of boiler makers, mechanical, electrical and general engineers, &c., carried on at Bristol under the style of "W. Pope and Co. and Batt and Phillips." The Directors include G. J. T. J. Parfitt, of Keynsham, Bristol, electrical engineer.

JAMES CHESTERMAN AND COMPANY (LIMITED).—This Company has been registered with a capital of £75,000, in £100 shares, to carry on the business of manufacturers of and dealers in engineers' tools, callipers, gauges, &c., and as mechanical, electrical, and general engineers, at Bow Works, Sheffield.

W. POPE AND SON (LIMITED).—This Company has been registered with a capital of £12,000 in £10 shares, to acquire the business of mechanical and electrical engineers carried on at Slough, by W. Pope and Son, and to develop and extend the same.

TINKERS' (LIMITED).—This Company has been registered with a capital of £50,000, in £10 shares, to carry on the business (among other things) of copper workers, steel converters, iron and steel plate manufacturers, iron and steel cable makers, electricians, and electrical, mechanical, consulting and general engineers, at Newton Hyde, Cheshire.

ALUMINIUM COMPANY (LIMITED)—The annual return of this Company, made up to November 17th, has been filed. The Company was registered on June 18, 1887, with a capital of £400,000, divided into 60,000 "A" and 20,000 "B" shares of £5 each, to acquire from Webster's Patent Aluminium Crown Metal Company (Limited) the patents of Mr. Jarvis Webster for the manufacture of alumina, aluminium and other metallic alloys, and also the patent rights of Mr. Hamilton Y. Castner, for the manufacture of sodium and potassium. At the time of making-up, all the shares had been taken up, and the 20,000 "B" shares issued as fully paid. Upon the 60,000 "A" shares, the full amounts have been called and all calls (£300,000) paid. The principal shareholders include the Right Hon. Arthur J. Balfour, M.P., and Gerald W. Balfour, M.P.

DAN RYLANDS (LIMITED).—The annual return of this Company, made up to December 12th, has been filed. This Company was registered on September 14, 1888, with a capital of £130,000, in £5 shares. The capital has since been increased to £275,000, divided into 20,000 ordinary and 35,000 preference shares of £5 each. 16,617 ordinary and 25,965 preference shares have been taken up, and 4,000 ordinary and 1,980 preference shares have been issued as fully paid. Upon the remaining 12,617 ordinary and 23,985 preference shares the full amounts have been called, resulting in the payment of £183,010.

NATIONAL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to December 9th, has been filed. The Company was registered on October 28, 1889, with a capital of £100,000, divided into 100 founders' and 199,000 ordinary shares of £5 each, to supply electricity generally. At the time of making up, 100 founders' and 10,425 ordinary shares were taken up, and the full amounts called, resulting in the payment of £51,920, and leaving £705 in arrears.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to December 13th, has been filed. The Company was registered on May 19, 1882, with a capital of £1,000,000, in £5 shares, to acquire the patents of Mr. J. Wilson Swan relating to electric lighting. At the time of making up, 78,949 ordinary and 19,750 fully paid shares have been taken up. Upon the 78,949 ordinary shares, £3. 10s. per share has been called, resulting in the payment of £279,851 10s., a sum of £3,530 has been paid on 1,201 forfeited shares, and £98,750 has been considered as paid on the 19,750 fully-paid shares.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended December 25th were £927, as against £871 for the corresponding period of last year, being an increase of £56. The total receipts for half-year amount to £21,584, against £19,457 in the corresponding period of 1891, being an increase of £2,127.

COMMERCIAL CABLE COMPANY.—The general offices in London of this Company have been removed from 18, Bishopsgate-street Within, to Bishopsgate House, 55 and 56, Bishopsgate-street Within, E.C.

CROMPTON AND CO. (LIMITED).—The Directors of this Company have declared interim dividends for the six months ending September 30th last at the rate of 7 per cent. per annum on the preference shares of the Company, and at the rate of 5 per cent. per annum on the ordinary shares.

CRYSTAL PALACE DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The annual general meeting of this Company was held at the registered offices, 4, Great Winchester-street, on Wednesday the 21st inst., Mr. Robert M. Meyer presiding. Mr. George Offor having read the notice of meeting, the Chairman announced that no accounts could be presented until about the month of March, as the Act of Parliament required them to be made up to December 31st and subsequently audited by the Board of Trade. The only business transacted was the appointment of J. D. A. Norris, Esq., as auditor for the ensuing year.

ELECTRICITY SUPPLY CORPORATION (LIMITED).—This Corporation notifies that the 5 per cent. interest payable to debenture holders on the 1st January next will be payable at the Union Bank of London on presentation of the coupons.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The share register of this Company is closed till January 1st next, as are also the share registers of the Wire Manufacturing Company (Limited) and the Foreign and Colonial Copper Depositing Company (Limited).

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—We understand that the report of the Directors of this Company announces that ample working capital has been provided for, that the works are completed

Hosted by Google

and have been furnished with a large supply of raw copper, and that practical operations have commenced. We have been unable to obtain a copy of the report from the secretary of the Company.

STOCK EXCHANGE QUOTATIONS.—The Stock Exchange Committee have ordered the £125,000 Four and a-Half per Cent. Perpetual Debenture Stock of the Brush Electrical Engineering Company (Limited), and the further issue of £94,100 Four per Cent. Mortgage Debenture Stock of the Eastern Telegraph Company (Limited), to be quoted in the Official List.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—This Company notify that the coupons due on January 1st on the Six per Cent. Mortgage Debentures will be paid at the National Provincial Bank of England on and after that date.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Dec. 23, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,254.

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square. MANCHESTER.

COUNTY BOROUGH OF BURNLEY.

TO ELECTRICIANS AND OTHERS.

The TOWN HALL and PARKS COMMITTEE of the BURNLEY TOWN COUNCIL invite TENDERS for the SUPPLY and FIXING of FITTINGS for the ELECTRIC LIGHTING of the interior of the Town Hall.

Drawings may be seen, and specifications, bills of quantities, and forms of Tender may be obtained at the Office of the undersigned, upon payment of one guinea, which will be returned on receipt of a bona-fide tender.

Sealed Tenders, endorsed "Electric Lighting, Town Hall," and addressed to the Chairman of the Town Hall and Parks Committee, must be delivered at the Town Clerk's Office, Town Hall, Burnley, on or before WEDNESDAY, the 18th day of January, 1893.

The Committee do not bind themselves to accept the lowest or any Tender, and parties tendering must do so at their own expense.

F. S. BUTTON, Assoc.M.Inst.C.E.,
Borough Surveyor.

Town Hall, Burnley, 21st Dec., 1892.

SPECIAL LECTURES.—A COURSE of TWELVE PRACTICAL LECTURES on "PRIME MOVERS FOR ELECTRICAL ENGINEERING" will be given by Mr. E. TREMLETT CARTER, at the SCHOOL OF ELECTRICAL ENGINEERING, 12, Prince's-street, Hanover-square, W., on TUESDAYS and THURSDAYS, from 6 to 7·30 p.m., commencing Tuesday, January 17th. Fee for the Course, £3. 3s.—Apply by letter, or personally, to Lecturer, at the above address.

SITUATIONS VACANT AND WANTED, &c.

ELECTRICAL.—WANTED, an experienced TRAVELLER for Lancashire and Yorkshire, to go amongst Ironmongers and others using Electrical Appliances. State in confidence, what experience, and where, also age and salary wanted.—Address, "ELECTRICIAN," care of B. Wheeler, Advertising Agent, Pall Mall, Manchester.

MESSRS. JOHNSON and PHILLIPS require a good ASSISTANT DRAUGHTSMAN, well up in Central Station and Switchboard Design.—Apply by letter, giving testimonials, experience and salary required, to the Works, Charlton, Kent.

WANTED FOREMAN in London Central Station; is expected to do repairs to Boilers and Engines, and to give most of his time. Apply by letter, stating age, experience, and wages required.—Address, 1136, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED, first-class DRAUGHTSMAN, accustomed to designing electric apparatus.—Apply by letter to "H.E.C.," 112, Belvedere-road, Lambeth, S.E.

APPOINTMENT WANTED by experienced electrical and mechanical ENGINEER, A.M.I.C.E., and E.E., as MANAGER or SUPERINTENDENT of installation work. Well up in dynamo design, shipwork, estimating, and management of men. Highest references.—Address, 1138, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

DESIGNER (Ornamental Work) REQUIRES DAY WORK, or will for permanent situation, give in exchange, several excellent original designs.—Address, "P.," 15, Oaklands-grove, Shepherd's Bush, W.

ENGINEER, with general experience in electric work and knowledge of application of science, desires an engagement.—"ALPHA," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

MISCELLANEOUS ADVERTISEMENTS, &c., CONTINUED ON NEXT PAGE.

M. THEILER & SONS,

Makers of High-class ELECTRICAL INSTRUMENTS of every description.

LECLANCHÉ BATTERIES.

LECLANCHE-BARBIER PATENT CYLINDRICAL AGGLOMERATE BATTERIES.

ALSO

ACCLOMERATE BLOCK AND POROUS POT BATTERIES. LECLANCHE ACCLOMERATE BLOCKS OF ALL SIZES.

THE LECLANCHÉ BARBIER CYLINDRICAL AGGLOMERATE WET CELL is the newest and most efficient form of Leclanché Battery. It is an open cell, all parts being instantly accessible, but so arranged as to render it practically a sealed one, with no evaporation or creeping salts.
No. 1.—E.M.F. 1·5 volts, I.R. 0·4 ohms. No. 2.—E.M.F. 1·5 volts, I.R. 0·8 ohms.

THE LECLANCHÉ-BARBIER CYLINDRICAL AGGLOMERATE DRY CELL possesses all the advantages of the wet one, with the special feature that not being sealed up (like all other dry batteries), any decrease in its E.M.F. can be at once restored by letting it absorb a little ammoniacal solution. The user can thus constantly maintain its efficiency at a trifling cost.
No. 1.—E.M.E. 1·5 volts, I.R. 0·5 ohms. No. 2.—E.M.F. 1·5 volts, I.R. 0·6 ohms.

SOLE AGENT FOR GREAT BRITAIN AND THE COLONIES—

R. AYLMER, 47, Victoria Street, LONDON, S.W.

ILLUSTRATED DESCRIPTIVE PRICE LISTS ON APPLICATION.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 764.—Vol. XXX. FRIDAY, JANUARY 6, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

In accordance with our usual custom, we publish in our first issue of a new year, various statistical tables, showing the state of different branches of the electrical industry. That such tables have a real value is evident, from the compliment which other journals have done us by following our custom. To draw up and send out circulars full of inquisitive interrogations is no difficult matter, but the result may be a sheet on which blank spaces are more numerous than the entries with which the table is supposed to be filled. To take a bundle of ready-made accounts, and to attempt to tabulate them, may result in a confusion of cross brackets, due to diversity in the form of such accounts. We have always endeavoured to restrict our annual tables to such details as may be reasonably expected from those to whom our inquiries are addressed, and when we hear from a secretary that "the lot of papers and forms sent from one source and another asking for information and wanting immediate reply would tax the resources of a large staff of clerks," we feel that we are not to blame; and it is not until we hear from another that "filling in replies to such queries as yourselves and others address to us costs both time and money, and we have not much to spare of either," that we begin to regret the compliment to which we have referred. Certain tables are printed in our columus as soon as is possible after the information has been published. The list of electric lighting provisional orders granted was thus given in our issue of September 30th last, and our analyses of the returns made by the London Electricity Supply Companies to the Board of Trade were given on July 8, 1892.

The amalgamation of the New Telephone Company with the National Telephone Company raises the question of the status of "The Association for the Protection of Telephone Subscribers." An agreement with this Association was entered into by, and was recorded on the prospectus of, the New Telephone Company. It was natural that this Association should have hailed with satisfaction the advent of a company which proposed to reform the greatly-grumbled-at service which is afforded in London, and the New Telephone Company, tempted by the considerations offered by the Association—viz., the suspension of negotiations with the Post Office, and the handing over *en bloc* of 1,700 members as a nucleus for future subscribers—promised certain concessions, amongst which a £12. 12s. rental was a prominent feature. In a letter to the Press, on behalf of the Association, it is asked: "If the improvement, extension and cheapening of the telephone, which has become a commercial necessity, has been crippled by the over-capitalisation of the existing monopoly, what benefit will the public derive from the strengthening of that monopoly, by the extinction of its only present competitor, at a cost of an addition of one million sterling to the capital on which telephone renters have to furnish by their subscriptions adequate interest?"

The discussion which has followed Mr. Human's letter on earthing the middle wire has been remarkable for its suggestiveness, rather than for useful information or definite addition to our knowledge. In his reply this week, Mr. Human clears up one or two misunderstandings, and reviews some of the correspondence. In our comments on his first letter, we remarked that we had hitherto refrained from advocating this system, since it appeared that the matter was hardly ripe for decision, or even for discussion. The subject divides itself into two sections, and the landmark between them is legally known as "the consumers' terminals." Our correspondents have considered the consumers' side, for the reason, no doubt, that central-station engineers, having mains in their charge under slightly different conditions, find that their experiences do not agree; we hope, on a future occasion, to record some of these.

It is hard to imagine what a dynamo or an arc lamp would be like if the air, instead of being an insulator, were a conductor; but a moment's thought is enough to show how important the passive properties of air are to electricians. Mr. Tesla, in an article we publish this week, maintains that, under certain exceptional circumstances, the air by no means possesses the convenient properties usually assigned to it. With alternating currents of great rapidity, it appears not only that the distribution of the current is altered in consequence of the "skin effect," but that the air near the conductors receives and dissipates part of the energy of the current. Some of the experiments Mr. Tesla mentions are very remarkable, although none of them are quantitative, and no definite conclusion can be drawn from them. The amount of energy which various air motions actually represent would be an interesting matter to find out, but we are not aware that anyone has yet measured the energy of a musical sound, or of any less regular air disturbance.

Hosted by Google

M. VIOLLE has communicated to the *Comptes Rendus* some interesting notes on the temperature of the electric arc. In an abstract which we print in another column, it will be found that he corroborates by spectro-photometrical observations the well-recognised view that the intrinsic brightness, and therefore temperature, of the arc is a constant. The chemical theory of the monomolecular and polymerised constitution of carbon makes the extraordinary latent heat of carbon vapour rational, for the watts expended or the volts lost at the incandescent surface of the positive carbon are thus accounted for, not only by the physical change of state from solid to vapour, but by a simultaneous change in the chemical constitution of the carbon.

THE results of M. VIOLLE'S calorimetric tests must be received with caution. His result agrees with that of ROSETTI, and confirms the extrapolated temperature which we ventured to deduce from the experiments of Profs. DEWAR and FLEMING. But M. VIOLLE appears to assume that the temperature of his button of carbon was not only constant throughout its mass, but that that temperature was the important one which he desired to measure. Careful observation of the crater of an arc shows that at the part of the surface at which volatilisation is taking place, this high temperature is only superficial. A sudden interruption of the current is followed by an apparently instantaneous fall of temperature, and a sudden diminution of the current is immediately followed by a very interesting development of flocculent patches of light, which quickly coalesce into a smaller crater. Theoretical considerations, moreover, indicate that since volatilisation takes place apparently from the solid without the intervention of the liquid state, only a mere layer of indefinite tenuity can take part in volatilisation, and it is highly probable that only an extremely thin layer of carbon is raised to the high temperature of volatilisation.

WE alluded some little time ago to the fact that the City of London Electric Lighting Company anticipated that they would be able to lay the fog fiend—or, at any rate, mitigate the terror of him—by an arrangement with the Dock Committee and others to send the Company timely warning of the approach of a fog bank. The idea showed some initiative, though we ventured to doubt the efficacy of the measures proposed, in view of the suddenness and sporadic distribution of a London fog. The condition of things which obtained on Wednesday last, for instance, was calculated to outwit the most elaborate organisation: Kilburn, dense mist; Hampstead, bright sunshine; Camden Town, fog; Broad-street, clear; Fleet-street, a villainous compound of mist and soot!

To put an eight-candle lamp into each boot while dressing in this weather is a great luxury, but not an expensive one. Boots being tolerably adiathermanous, the temperature soon rises, and on the right side of the soles. Those who are not early risers, and who do not provide their servants with electric light in the basement, will do well, when there is no fog, to connect the lamps in series, since if no other lamps are on, the meter will probably fail to start. But if it does, the cost will not exceed about one-twentieth of a penny, five minutes being ample, the cost of a week's boot-warming being, therefore, under a halfpenny.

Cardiff.—Acting under the advice of Mr. W. H. Massey, the Town Council have decided to adopt an alternate current transformer system of distribution at a cost of £32,500.

Earthing the Middle Wire.—According to *L'Industrie Electrique* the Compagnie Continentale Edison have earthed their middle wire for more than a year with satisfactory results.

Kimberley Exhibition.—The Kimberley Exhibition was formally closed by the Mayor on the 8th ult. The Exhibition has not been a financial success, the accounts showing a deficiency of £14,000.

Hull.—The municipal central lighting station is to be formally opened on the 16th inst., by the Mayor. On the following day, the Mayor will open an Electrical Exhibition in the Sessions Court, Council Chamber and Library.

Heckmondwike.—At Monday's meeting of the Local Board a recommendation of the Electric Lighting Committee to empower the clerk to take the necessary steps for obtaining the sanction of the Local Government Board to the electric lighting scheme was approved.

The Electric Lighting of Malta.—Mr. W. H. Preece arrived at Malta on Friday last from London to confer further with the local Government on the proposed installation of the electric light. He was accompanied by Prof. George Forbes and Mr. Henry Edmunds.

Southport.—The Town Council has by a large majority resolved to reject a £15,000 scheme for developing the foreshore, and has adopted instead an enlarged scheme estimated to cost £20,000. The adopted scheme embraces amongst other items an electric tramway.

Institution of Electrical Engineers.—At the next meeting of the Institution on Thursday, the 12th, the discussion on Dr. Fleming's Paper will be resumed. In consequence of the unavoidable absence abroad of Mr. Preece, the new President, he will deliver his Inaugural Address on the 26th inst.

India-rubber.—The following is an extract from a Reuter's telegram received from the Imperial British East Africa Company from Mombasa :—" The india-rubber season has been very good, notwithstanding the drought, and the customs returns from this product have been unusually large."

Bewdley.—Bewdley, a quiet, old-fashioned town of less than 10,000 inhabitants, has appointed a committee to make inquiries as to the utilisation of the river Severn for electric lighting purposes, notwithstanding that one member of the Town Council rudely characterised the whole idea as " bosh."

Preston.—At a recent meeting of the Town Council, Alderman Hibbert drew attention to the electric light pillars that were being put down in Fishergate. He objected to the character of the castings, and said they were not such that any municipality ought to be satisfied with. They were " coarse ness itself.

Prime Movers for Electrical Engineering.—A course of 12 practical lectures on this subject will be delivered at the School of Electrical Engineering, 12, Prince's-street, Hanover-square, W., by Mr. E. Tremlett Carter. The course will commence on Tuesday, January 17th. For further particulars see our advertisment columns.

Obituary.—The death is announced of M. Amédée Guillemin, a popular science writer. He was born at Pierre (Saône-et-Loire) in 1826, was educated at Beaune and Paris, taught mathematics, and then adopted journalism, and in 1861 began a series of popular treatises on astronomy and physics.

The Electric Transmission of Power.—The Compagnie de l'Industrie Électrique are laying down a 365 H.P. transmission of power plant at the Biberist paper mill, in the canton of Soleure. The fall from which the power is obtained is 17½ miles distant. Two Thury generators, arranged in series and

Hosted by Google

coupled direct to Escher-Wyss turbines, supply current at a pressure of 6,800 volts. The plant will be ready by March.

Coast Communication.—In the interim report which the Royal Commission on Coast Communication has drawn up it is recommended that five lightships and a certain number of rock lighthouses shall be connected with the coast by telegraph cable. Those places will be selected which furnish the best opportunities for testing the possibility of such communication, and at the same time reveal the extent to which it is likely to be valuable in saving life or property.

Mozambique-Laurenço Marques	January 5, 1893

Institution of Civil Engineers.—Monday last was the seventy-fifth anniversary of the Institution of Civil Engineers, which was established for the advancement of mechanical philosophy, and which ten years later was incorporated by Royal Charter under Great Seal. It consists to-day of 5,122 corporate members, 389 associates and 830 students, together 6,341. —At the last meeting of the Institution, before Christmas, the Council Room was brilliantly illuminated with glow lamps, and other parts of the building were being wired for electric light.

The Electric Lighting of South Kensington.—A provisional agreement has been entered into, subject to its confirmation by Parliament, by which the Chelsea Electricity Supply Company agree to sell and transfer to the Kensington and Knightsbridge Electric Lighting Company all the rights and powers obtained by them in 1889 for the electric lighting of South Kensington. The sum to be paid by the Kensington and Knightsbridge Company for these rights is £7,000, and the transfer is to take place within one month after the agreement has received Parliamentary confirmation.

Association for the Improvement of Geometrical Teaching. —The general meeting of this Association is to be held at University College, Gower-street, on Saturday, January 14th, at 11 a.m. and 2 p.m. After the conclusion of the formal business, Mrs. Bryant, D.Sc., will give "A Model Lesson on Geometry, as a basis for discussion," and papers will be read by Mr. G. Heppel, M.A., on "The Use of History in Teaching Mathematics," and by Mr. F. E. Marshall, M.A., on "The Teaching of Elementary Arithmetic." All interested in the objects of the Association are invited to attend.

Telephone Wires.—At a recent meeting of the St. Helens Paving Committee an application from the Liverpool Corporation for permission to erect ten telephone poles along the Rivington-road was read. The borough surveyor thought the wires should be put under ground, and thought it time that the National Telephone Company, whose trunk wires in St. Helens are overhead, should put them under ground. It was decided that permission should be given, subject to the Liverpool Corporation removing the poles if required by the St. Helens Corporation, and notice was given of the intention of the St. Helens Corporation to have in the near future all telephone wires under ground.

The South Staffordshire Electric Cars.—On Saturday last the electric system of the South Staffordshire Tramway Company was opened with no little ceremony. The invited guests included the Bishop of Lichfield, the Mayors of Walsall, Wednesbury, and West Bromwich, and the members of the governing bodies of the district, the Chairman and Directors of the Company, the Directors of the Electric Construction Corporation, the electric equipment contractors. The new cars have since Saturday been extensively patronised by the public, but on Tuesday morning the trolley wire at the junction of Park-street with the Bridge, Walsall, snapped, causing a temporary disarrangement of the service.

Cheltenham.—The adjourned discussion on the report of the Electric Lighting Committee recommending the adoption of a scheme for the introduction of a high-pressure system of supply, and deferring for the present the question of lighting the streets with electricity, was resumed at the meeting of the Town Council on Monday last by Mr. Waghorne, who moved an amendment referring the matter back to the Committee, with a request that they should take further professional opinion upon the scheme recommended by the Committee on the advice of the borough surveyor and Prof. Ayrton. Mr. Norman, Chairman of the Committee, eventually accepted the amendment, which was agreed to.

Presentation to Mr. C. E. Spagnoletti.—A meeting was held at the offices of the Great Western Railway Company's Telegraph Department, on the 28th ult., to present Mr. C. E. Spagnoletti with a testimonial upon his retirement from active service. The presentation consisted of an illuminated address and several articles of plate, subscribed for by the members of the Telegraph and Electric Light Departments. The chair was taken by Mr. H. T. Goodenough (Mr. Spagnoletti's successor), who, in requesting Mr. Spagnoletti to accept the gift of the members of the department, claimed for Mr. Spagnoletti the title of "Father of Railway Telegraphy." Mr. Spagnoletti, after thanking the staff, gave a brief *resumé* of his career, with special reference to the history and development of railway electrical appliances.

Electrolytic Action in Condenser Tubes.—Some brass condenser tubes in the U.S. cruiser "Baltimore," after being in service for a year or more, were, says *Engineering*, found to have experienced a peculiar change. In many places the metal was changed to almost pure copper, of a spongy texture, the zinc having completely disappeared. An investigation showed the probable cause of the failure to have been an electrolytic action between the tin lining of the tubes and the brass, the sea-water circulating through the condenser forming the electrolyte. Had the tin-coating remained perfect, no corrosion would have resulted; but the mud and grit carried in suspension through the condenser cut away the tin-coating in spots, and it was at these spots that the change of the metal occurred. It was concluded that if the tubes had not been tinned at all they would have remained intact.

The Electrical Utilisation of Water Power in Japan.—The Japanese are apparently determined to extract the maximum of use out of their public works, if the Kioto Canal is any criterion. The total length of the canal is $6\frac{7}{8}$ miles, and in its short course it passes through three tunnels. At a distance of $5\frac{1}{4}$ miles from Lake Biwa the canal is divided into two parts, one being practically continuous at the same level as the main portion, and the other being at a level of 118ft. below. The upper branch is used entirely for irrigation purposes, while the lower branch receives all the boat traffic from the upper main canal. Instead of having a succession of locks from the upper to the lower levels, a cable railroad has been built to connect them. The water from the upper canal is led through three 36in. pipes, 1,300ft. long, to a power-house, and is delivered to a set of Pelton water-wheels at a head of 100ft. These wheels supply the power for the cable road, and also drive dynamos which supply current in Kioto for all sorts of purposes.

The Effect of Electrical Excitation on Salivary Secretion. —In a Paper recently communicated to the Académie des Sciences (*Comptes Rendus*, Tome CXV., No. 24, page 1,103), M. Wedensky describes in considerable detail some experiments carried out by him with regard to the influence of amperage and frequency on the secretions of the submaxillary gland. A first series of experiments showed that the best frequency for provoking secretion was about 40, and that the longer the current was applied the lower did the best periodicity become. Starting with a frequency considerably below the best, the curve rises slowly and almost in a straight line, and finally turns over (100-250 $\sim$) and becomes parallel to the abscissa. In a second series of experiments, the frequency was varied during one and the same application. By decreasing the frequency the gland, which had previously ceased to secrete, could be made to do so again, and even for a time renew secretion at a higher frequency. Much the same result was obtained by altering the current. There was a considerable time lag between the alteration of the irritant cause and the corresponding alteration of the secretory effect.

The Bressa Prize.—By the will of Dr. Cesare Alessandro Bressa, a sum of money was left to the Royal Academy of Sciences of Turin, for a prize to be given at intervals for the best scientific work written, or the most important discovery made, during the preceding period of four years. It is now announced by the Academy that the last term of four years closed on December 31st, 1890, when the prize was secured by Prof. Hertz, and that a new term, dating from January 1, 1891, to December, 31, 1894, is now in progress. Scientific men and inventors of all nations may compete. The prize is worth 10,416fr. Those who desire to compete must declare their intention of doing so within the time above mentioned, by means of a letter addressed to the President of the Academy, and must send the work which they offer for adjudication. The work must be printed; manuscripts are not considered. The works of unsuccessful competitors will be returned to them, when asked for, within six months from the awarding of the prize. The last paragraph of the notice issued by the Academy on the subject of this competition states that:—"The Academy gives the prize to the scientific man considered most worthy of it, even if he has not presented himself at the competition."

The Glasgow Tramways.—A sub-committee of the Glasgow Town Council have published their report on the different modes of tramway traction. The sub-committee state that they have gone carefully into the offers for a complete system of overhead trolley electric traction to be worked from one central station. The routes cover about $6\frac{1}{3}$ miles of double track. The Committee conclude from the offers that a substantial and complete installation, including cars for a six-minutes service and equipment of lines, would cost about £10,000 per mile of double track, exclusive of ground. A complete equipment for horse traction on a similar service could be put down for £5,000 per mile of double track. The cost of a cable system is set down at about £20,000 per mile of double track. The Committee state that while they clearly recognise the advantages of electric traction, they are, at the same time, fully alive to its disadvantages and the difficulties which would have to be faced in the event of its adoption. Taking everything into consideration, they are of opinion that the inducements it offers, as compared with horse traction, are not sufficient to justify the acceptance of any of the offers for an electric installation. At the same time they would recommend that the further development of all forms of electric traction be carefully followed. The cable system is to have further special consideration by the Committee.

Brussels.—As we recently stated, the electric lighting contract between the India Rubber, Gutta Percha and Telegraph Works Company of Silvertown, is at last signed. The following particulars of the plant to be employed in the pioneer station may be of interest:—The chief feature in the scheme lies in the plan of distribution, the cables *throughout* being insulated with vulcanised india-rubber, and run in separate cast-iron pipes. The station, when finally completed, will have six units of 500 H.P. each, any one unit, if required as a reserve, or for exceptional loads, for a short time being capable of working up to 625 H.P. The battery of accumulators will eventually be increased to 1,250 16-c.p. lamps normal capacity. The site of the station is on that at present occupied by the Eglise Ste. Catherine, Place Ste. Catherine, near the Boulevard Anspach. The church is to be removed by February next. The boilers are safety multitubular, with 226 square metres heating surface each, with pumps and economisers complete. The engines are two horizontal, compound, condensing Sulzer type, by Carels, of Ghent, 500 H.P. effective, each capable of working up to 625 H.P. effective, if required. The four dynamos are slow speed multipolar machines, rope driven, two to each engine. The distribution is on the three-wire system. The station is to be in complete working order by October next. The current is to be sold by meter, and the Silvertown Company are to work the station for two years after delivery to the satisfaction of the town.

Electric Traction for Railways.—Amongst the Foreign Abstracts published by the Institution of Civil Engineers we note an abstract of a Paper by a German engineer named Bork, who appears to have a very high idea of the future of electric traction as applied to railways. Electrical machines with a high-pressure current have, he says a far higher efficiency than locomotives, allowing 10 to 17 per cent. loss in transmission. Further, at high speeds, electric traction is much more efficient than locomotive traction, *e.g.*, to drive a train at a speed of 50 miles per hour up a gradient of 1 in 200 by electricity requires only half the energy that it does in the case of locomotive traction. He estimates that a stationary engine will only require 1·76lb. of coal per I.H.P.H., against 3·3lbs. in the case of a locomotive. For passenger and express trains with a speed from 30 to 50 miles per hour, the author makes out that only 60 per cent. of the energy required in the case of locomotive traction is needed by electric traction. The author then shows the gain of electric traction over locomotive traction for express service by supposing a train of 60 tons travelling at 50 miles per hour on a gradient of 1 in 200, which would need 548 I.H.P. for locomotive traction, and 280 I.H.P. for electric traction, or a gain of 51 per cent.; for a speed of 33 miles per hour, the gain is 69 per cent., or a mean gain of 60 per cent. for an average speed of 42 miles per hour. Cost of loco-traction per 1,000 miles, £33·7; cost of electric traction per 1,000 miles, £22·4; gain $= \frac{22{\cdot}4}{33{\cdot}7} \times 100 = 66$ per cent. Taking into account the interest on capital, depreciation, &c., together with the increased frequency of the trains and their greater speed, we have a gain over the present system of $\frac{23{\cdot}5}{33{\cdot}7} \times 100 = 70$ per cent. The author concludes by advising the construction of an experimental line, or section of a line for which he gives full details as regards costs, and so forth.

Impending Electric Railway Patent Litigation.—It appears from a circular recently issued by the General Electric Company says the *Electrical World* of New York, that it is on the warpath in earnest in endeavouring to obtain control of the electric railway field. Owning as it does the inventions of Edison, Thomson, Van Depoele and Sprague, who are recognised as the creators of the modern electric railway, it certainly appears to stand some chance of covering the field quite effectually. The circular gives the list of lawsuits which the Company has instituted against electric railways in different parts of the country on whose roads some devices are used for which the General Electric Company claims to have the patents. Among the subjects of the pending suits are the following:—The under-running trolley, covered by four patents of Van Depoele, dating from 1889 to 1892, the latter especially being claimed to be a "broad patent for under-running, upward-pressing contact trolley;" electric motor trucks, covered by three patents of Sprague, the earliest dated 1885, covering motors which are sleeved on the axle and supported by springs at the other end, also for individual motors for separate axles; duplicate controller switches at opposite ends of the car, reversing motor and regulating resistance of motor circuit, a recent patent of Sprague; trolley having constant pressure with pole at varying angles, an early patent of Van Depoele; arched suspenders for electric railway trolley wires, three patents of Van Depoele; lightning arrester, Thomson's patent, 1885; constant potential regulation by a compound dynamo, Edison's patent, 1882; overhead switches and arched suspender and pull-off for trolley wires, five patents of Van Depoele. The circular concludes with the statement that the Company believes that all the apparatus and devices employed in the modern electric railway are broadly covered by these patents, and that the Courts will so determine them. There is little doubt that if the Courts do decide all these cases in its favour, the General Electric Company will have a practical monopoly of the electric railway interests for some years to come, as there appears to be little left for anyone to use in the construction of an electric railway which would not come under one or the other of these patents. For the present we will reserve our opinion as to the probable outcome of these suits. That the fight will be a bitter one is not at all unlikely, and perhaps, as in some other cases, it will last about as long as the remaining life of some of these patents.

ELECTROMAGNETIC THEORY.—XLII.

BY OLIVER HEAVISIDE.

(*Continued from page 241.*)

§ 178. Using the same kind of point-source, let it act intermittently and alternatingly; say, on positively for an interval α, then off for an interval β, then on negatively for an interval α, followed by off for an interval β, and so on recurrently, like positive and negative applications of a battery with dead intervals. The result is, by the last case, to divide the spherical space occupied by the disturbances at a given moment into concentric shells, of depths $v\alpha$ and $v\beta$ respectively. In the latter is no disturbance, since they correspond to the dead intervals. In the former are the steady displacements appropriate to their distance from the source, consecutive shells being positive or negative according to the state of the source when they started from it. On their boundaries are electromagnetic sheets generating these steady states continuously on one side, and destroying them on the other.

Next, do away with the dead intervals, so that the applied force is like that of a common reversing key, first positive of full strength, and then negative of full strength, but without any interval. The result is to completely fill up the sphere of disturbance, the successive shells of depth $v\alpha$ containing steady fields—alternately positive and negative—being brought into contact, and only separated from one another by the electromagnetic sheets. This may be considered rather an unexpected result. Our impressed force is periodic, but expresses the extremest form of variation, namely discontinuities, and is only expressible simple-harmonically by an infinite series of simple-harmonic forces of all frequencies from zero to infinity. But only when the impressed force varies is electromagnetic disturbance generated, so that when in the above manner we confine its variations to be momentary, the electromagnetic disturbances are also momentary, with the consequent result that we have our dielectric occupied by quite steady states of displacement separated by infinitely-thin electromagnetic shells. The latter travel. The steady states also appear to travel, but do not really do so. They are being continuously generated and destroyed at their boundaries, but are quite steady elsewhere.

If the impressed force vary simple-harmonically instead of discontinuously, the result is less simple. We find that there is no clean separation into steady states and electromagnetic waves, the two being mixed inextricably. We can see this by substituting for the simply periodic variation of the force a very great number of constant forces of small duration and of different strengths, so as to roughly imitate the simple-harmonic variation. Every discontinuity in the force will behave in the way described, and the final result of the superimposition of effects, when we proceed to the limit and have continuous simple-harmonic variation of the force, is a train of simple-harmonic waves proceeding from the source. They are not pure electromagnetic waves, and there is no steady state anywhere. The wave-length λ is given by $\lambda = v\tau$, where τ is the period of the impressed force, or the reciprocal of the frequency. The electric and magnetic forces are simple-harmonic functions of the time everywhere, right up to the extreme wave-front of the disturbance, where, of course, is an electromagnetic sheet following a different law. But should the source occupy a finite spherical space, then the bounding sheet becomes a shell, of depth equal to the diameter of the sphere, as before described. Now the steady fields become insensible at a great distance in the discontinuous case; to correspond with this we have the fact that the simple harmonic waves tend to become pure as they expand. The greatest departure from the pure state is round about the source. Here the frequency becomes a matter of importance. When very low, the wave-length is great, and we should, therefore, have to go a great distance to find any sign of wave-propagation. Moreover, the waves themselves would be exceedingly weak. Only round the source is there sensible disturbance, and it is practically the steady displacement appropriate to the momentary state of the source, accompanied by a weak state of magnetic force connected with the displacement nearly in the instantaneous manner. That is, the time-variation of the displacement is the electric current, and the displacement itself is sensibly that of the static theory. Under these circumstances there is next to no waste of energy.

But by increasing the frequency we can completely alter this state of things. For we increase the rate of change of the impressed force, and therefore the strength of the electromagnetic waves generated, for one thing. Besides this, we can bring the region of electromagnetic waves nearer to the source, and so contract the region in which the displacement was approximately static as much as we please. In the limit with very great frequency we have nearly pure electromagnetic waves close up to the source. The waste of energy increases very rapidly with the frequency, varying as its fourth power with simple-harmonic waves. The extremest case of waste is that of a discontinuity, already mentioned, as when setting up the steady state we waste half the work done, and then, when the force is removed, waste the other half.

§ 179. When the sphere of impressed force is of finite size, another effect comes into view of a somewhat striking character, of which the theory of a point-source gives no information. By increasing the frequency sufficiently, we shall reduce the amplitude of the external vibrations, and on reaching a certain frequency depending upon the size of the sphere, they will entirely vanish. That is, at a certain frequency, a simple harmonic impressed force, acting uniformly within a spherical space in a dielectric, produces no external effect whatever. The vibrations are stationary or standing, and are purely internal, or confined to the sphere itself. By general experience of statical problems this would seem to be impossible. But we must expect to find strange manners when we go into strange lands.

This strange behaviour arises from the general electromagnetic property that the true source of disturbances due to impressed force (electric or magnetic) is the curl thereof. The impressed force itself, on the other hand, is associated with the supply of energy. (*See* § 87.) In the present case the surface of the sphere of impressed force is the seat of its curl, its intensity varying as the cosine of the latitude, if the polar axis be parallel to the impressed force; and consequently, as already described for the case of setting up the steady state, the electromagnetic waves proceed both ways from the surface at which they originate. The train of waves going inward contract, then cross at the centre and expand again. We have, therefore, two trains of outward waves, and the external effect may be imagined to be due to their superimposition. That they may sometimes assist and sometimes partly cancel one another, according to relative phase, may be readily conceived, and the theory indicates that at any one of an infinite series of definite frequencies there is complete cancellation externally. This refers to the simple-harmonic state. There is always an external effect initially, at any frequency—namely, the initial electromagnetic shell of depth equal to the diameter of the sphere of impressed force, because it consists entirely of the beginning part of the first outward wave, the second one only reaching to its rear; but on the inner side of this shell there may be no disturbance, except within the sphere of impressed force. The waste of energy is not continuous at the critical frequencies, but consists merely of the energy in the initial shell. The impressed force works continuously, but as much positively as negatively within a period, so that it is inactive on the whole.

Effects of the above described kind are principally remarkable from the contrast they present towards more familiar effects, especially those of a statical kind. The behaviour of electrification on a sphere may be taken as an illustrative contrast. We know that if we have a spherical surface in a uniform dielectric covered with electrification, the displacement is partly internal and partly external. Only when the electrification is uniformly spread does the displacement vanish internally, and become wholly external. This was formerly explained by the inverse-square law. Every element of electrification was supposed to exert force equably in all directions round itself, internally as well as externally, and a mathematical consequence of this is the complete cancellation of the internal force when the electrification

Hosted by Google

is uniformly spread on the surface of a sphere. The same reasoning was applied when the sphere was not of the same nature as the external medium—when it was a conductor, to wit. Now the internal force is also zero in this case. Moreover, it is zero whatever be the nature of the internal material (without electrical sources). But it is certainly untrue that the electric force due to a point-source of displacement is the same in all directions around it when the medium is not homogeneous. So the reason for the absence of internal force is entirely wrong, although it seems right in one case, viz., that of homogeneity. The true, and sufficient, and comprehensive reason for the equilibrium, and the absence of internal force is the satisfaction of the second circuital law when the external electric force is perpendicular to the surface. This is independent of the nature of the internal matter, and is obviously to be preferred to a hypothesis that is only valid sometimes. Varying the internal material will make the law of spreading of force be different in any number of ways, and, if we like, different for every element of electrification, by arranging various kinds of heterogeneity. But independently of this, we might vary the law of force in many ways in special cases. Thus, in the case of a uniform spread of electrification on a sphere, we may imagine the displacement from any particle of electrification to radiate in any symmetrical manner that will give zero displacement inside and a uniformly radial displacement outside. The simplest case after the usual uniform spreading in all directions, is a planar spreading. Let every element of electrification on the surface send out its displacement in the tangential plane only, though equally in all directions in that plane. This will give the correct static result. It is not altogether a fantastic example, for we can make an electromagnetic problem of it by letting the electrified surface expand at the speed of light. Then the assumed law of spread is the actual law, for every element of electrification is the core of a plane electromagnetic wave. The resultant magnetic force due to all the waves, however, is zero, and the resultant electric force is as in the static problem. (See §§ 61 and 164.)

Now when we have vibrating electromagnetic sources on a spherical surface producing electromagnetic waves simple-harmonically, we also in general have both internal and external effects, for there is an internal as well as an external train of waves. But whilst they cannot cancel internally, they may do so externally. Here is one contrast with the static problem, and along with it is another, viz., that it is the nature of the external medium that is now indifferent (with a reservation), whereas in the static problem we have independence of the nature of the internal medium. The reservation hinted at is connected with the initial uncancelled electromagnetic shell. The external medium should allow it to escape, or absorb it somehow, so that it will not interfere with the effects under consideration. To regard the zero external effect as being actually due to the coexistence of two trains of waves which cancel one another is merely a mathematical artifice, however, because neither train of waves exists. If they did exist we should have to vary their nature to suit the constitution of the external medium, just as in the problem of static equilibrium we require different laws of force to suit the nature of the internal medium. The comparison of the static with the kinetic problems show a complete reversal of relations as regards nternal and external.

What we can do with a single surface electromagnetic source we can repeat with others inside it. We see, therefore, that the whole sphere of impressed force may be filled up with vibratory sources of the most vigorous nature without producing any (except initial) external effect, if their periods be properly chosen in relation to their situation, which problem admits of multiple solutions. This is suggestive as regards the stores of energy bound up with matter.

§ 180. In the above very little has been said about the distribution of electric and magnetic force from part to part of an electromagnetic wave. This varies greatly in different kinds of waves, and cannot be explained without the formulæ. But there is one very important property of pure electromagnetic waves (which also holds good, more or less approximately, in general) which may be described at present. As already mentioned, the electric and magnetic energies are equal in a pure electromagnetic wave. Now the density of the electric energy is $\frac{1}{2}cE^2$, if E is the electric force (intensity), and that of the magnetic energy is $\frac{1}{2}\mu H^2$. If we equate these, we obtain a relation between E and H. Thus

$$\frac{1}{2}cE^2 = \frac{1}{2}\mu H^2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Also $$\mu c v^2 = 1. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Therefore $$E = \pm \mu v H. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The positive or negative sign depends on which way the wave is going. Disregarding this, the electric and magnetic forces have a constant ratio. They are therefore in the same phase, or keep time together in all their variations. Along with this, they have the property of being perpendicular to one another (that is, **E** and **H** are perpendicular, not E and H), and their plane is in the wave-front, or the direction of motion of the wave is perpendicular to **E** and to **H**. It is the direction of the flux of energy. These properties hold good in all parts of a pure electromagnetic wave, although the magnitudes and directions of the electric and magnetic forces may vary greatly from one part of the wave to another.

The above is also the state of things that obtains, more or less perfectly or imperfectly, in long-distance telephony over copper circuits of low resistance, and by lowering the resistance per mile we may approximate as nearly as we please to the state of pure electromagnetic waves. It is the self-induction that brings about this state of things, showing such a contrast to the more familiar relations between the electric and magnetic forces on circuits in general. Like a kind of fly-wheel, the self-induction imparts inertia and stability, and keeps the waves going. It is the long-distance telephoner's best friend who was, not many years since, spurned with contempt from the door. Some people thought there was a very absurd fuss made about self-induction, and that it was made a sort of fetish of; so, knowing no better, they poured much cold water on the idol. But, whatever opinions we may hold regarding their competence as judges, there can be no question about the stern logic of facts. Self-induction came to stay, and stayed it has, and will stay, having great staying power. Whatever should we think of engineers who declined to take into account the inertia of their machinery? There was also some considerable fuss made about a supposed law of the squares, or KR law as it was or is called, according to which you could not telephone further than KR = such or such a number, because the speed of the current varied as the square of the length of the line, or else inversely. But in spite of the repeated attempts made to bolster up the KR law, the critical number has kept on steadily rising ever since. I see now that it has gone up to 32,000. But it need not stop there. Make your circuits longer, and it will go up a lot more.

As regards the ether, it is useless to sneer at it at this time of day. What substitute for it are we to have? Its principal fault is that it is mysterious. That is because we know so little about it. Then we should find out more. That cannot be done by ignoring it. The properties of air, so far as they are known, had to be found out before they became known.

(To be continued.)

THE RATE OF PROPAGATION OF ELECTRIC WAVES IN AIR AND IN CONDUCTORS.*

BY ED. SARASIN AND L. DE LA RIVE.

In a former series of investigations on the propagation of Hertzian electric waves through air† we came to the conclusion that the rate of propagation of such waves through air was sensibly the same as along conducting wires. The beautiful experiment of Hertz, which we contented ourselves with repeating under almost identical conditions, consists, as is

* From the *Comptes Rendus*, December 26, 1892, p. 1,277, Vol. CXV., No. 26.

† *Comptes Rendus*, March 31, 1891, Vol. CXII., No. 13. Also *The Electrician*, April 10, 1891, p. 701, Vol. XXVI.

Hosted by Google

known, in causing electric waves to impinge normally upon a large plane metallic surface, and in observing by means of a circular resonator moved along the normal to the centre of the mirror the interference of the direct and reflected waves. The metal shield which did duty as a mirror in our first investigations had almost the same dimensions as those of the shield employed by Hertz himself, *i.e.*, 2·8m. × 3m.; dimensions too small to allow of the observation of more than one node in front of the mirror with resonators 50cm. and more in diameter. We in-

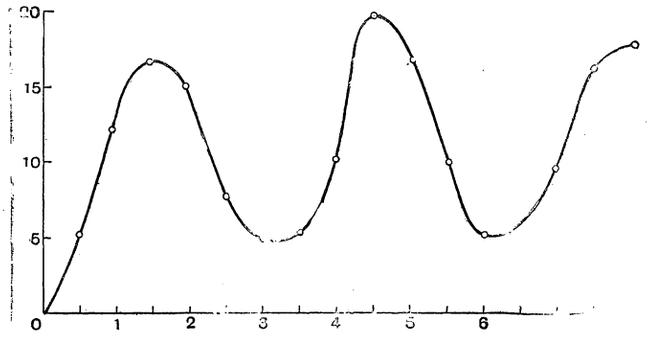

FIG. 1.

creased the size of our mirror as much as our laboratory permitted us to, making its breadth 5m., and in this way improved the experimental conditions for small circles of 35cms. diameter and less. We did not, however, get much advantage with larger circles. But the experimental demonstration of the equality of the rate of propagation in air and in wires was not altogether satisfactory in the case of large wave-lengths, and as Hertz* himself remarked, it was desirable that this should be done in a definite manner by experiments on a much larger scale, with a mirror of sufficiently large size to permit of the observation with a 75cm. circle of several interference nodes and antinodes. These conditions we have realised to the best of our ability in the course of a fresh series of researches, which we have the honour of presenting to the Academy to-day.

The great difficulty was to find sufficient room. Thanks to the courtesy of the Geneva Municipality, who placed at our disposal a still vacant space in the large turbine hall of the Geneva power works, we were enabled to do what we wanted. Against one of the walls of the building was placed a large metal screen, 8m. high by 16m. broad, consisting of zinc sheets 2m. × 1m. nailed over one another on a wooden frame. To

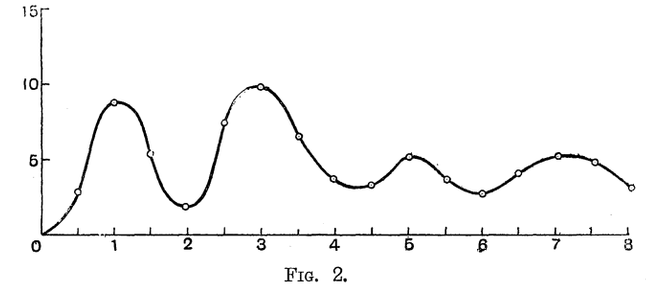

FIG. 2.

enable us to observe the secondary sparks along the normal to the centre of the mirror—that is to say, along a line 4m. from the ground—we erected in front of the mirror a bridge 10m. long and 1·5m. broad, supported on three wooden trestles, and surmounted by a light framework of laths covered with black paper, and forming a completely dark tunnel. In this dark-room was placed the optical bench, which we have previously described, the length of which was increased to 9m., and along which the resonators were moved, their centres being kept normal to the middle of the mirror. The primary conductor was arranged 15m. away from the mirror, elevated on a support and facing the centre of the mirror. It consisted as before of two brass rods 7mm. thick, connecting two spheres 30cm. in diameter. The new arrangement, which we had previously adopted for the oscillator, and which consists in producing the primary spark in oil instead of in air*, appreciably facilitated this experiment by greatly increasing, as we have stated, the secondary spark in length and brilliancy, thus affording an opportunity for micrometric measurements of the spark gap. The resonators which we successively employed were provided with micrometer gauges, the screws having a $\frac{1}{4}$mm. pitch, and the scale being such that we could read directly a $\frac{1}{100}$th of a millimetre. In this manner we determined at equal intervals from the mirror the size of spark gap necessary to prevent sparking. Taking distances from the mirror in metres as abscissæ, and micrometer gauge readings in hundredths of a millimetre as ordinates, curves (Figs. 1 and 2) were obtained respectively with the 0·75m. and the 0·5m. circle. These two circles, which only yielded imperfect results with 3m. and 5m. mirrors, and on which we, for that very reason, engaged in fresh investigations, gave with the large mirror results quite comparable with those obtained with the smaller circles in our previous experiments. We deduced the wave-length of each resonator, either by observation of the nodes and antinodes in the two principal positions of the circle, parallel to the mirror (in the plane of the wave) or horizontal (in the plane of vibration), or by plotting the curve of the decreasing and increasing intensities of the secondary sparks.

The question of the equality of the rate of propagation in air and in wires appears to us to be definitely settled by the use of the large mirror. The 0·5m. circle, in fact, gave us three very well defined antinodes and three nodes. The 0·75 circle gave three antinodes and two nodes, equally well defined. The mean of a large number of determinations for the two circles is as follows :—

	1st Antinode.	1st Node.	2nd Antinode.	2nd Node.	3rd Antinode.	3rd Node.
	m.	m.	m.	m.	m.	m.
50cm. circle ...	1	2	3	4	5	6
75cm. circle ...	1·5	3	4·5	6	7·5	—

These are identical with those obtained by us with the same circles along wires. Thus the conclusions arrived at by us in our previous researches are fully confirmed for large wave lengths, viz. :—

The secondary resonator has a fixed wave length, whatever may be the size of the oscillator, the strength of the oscillation alone varying.

One quarter of the wave length of a circular resonator is very approximately equal to twice its diameter.

In the case of normal reflection the first node is exactly at the mirror.

Finally, our principal result is that—

The rate of propagation of electric waves is the same in air as along conducting wires.

ON THE DISSIPATION OF THE ELECTRICAL ENERGY OF THE HERTZ RESONATOR.†

BY NIKOLA TESLA.

Anyone who, like myself, has had the pleasure of witnessing the beautiful demonstrations with vibrating diaphragms which Prof. Bjerknes exhibited in person at the Paris Exposition in 1889, must have admired his ability and painstaking care to such a degree as to have an almost implicit faith in the correctness of observations made by him. His experiments "On the Dissipation of the Electrical Energy of the Hertz Resonator," which are described in the issue of December 14th of the *Electrical Engineer*,‡ are prepared in the same ingenious and skilful manner, and the conclusions drawn from them are all the more interesting as they agree with the theories put forth by the most advanced thinkers. There cannot be the slightest doubt as to the truth of these conclusions, yet the statements which follow may serve to explain in part the

results arrived at in different manner ; and with this object in view I venture to call attention to a condition with which, in investigations such as those of Prof. Bjerknes, the experimenter is confronted.

The apparatus, oscillator and resonator, being immersed in air, or other discontinuous medium, there occurs—as I have pointed out in the description of my recent experiments before the English and French scientific socities—dissipation of energy by what I think might be appropriately called *electric sound-waves or sound-waves of electrified air*. In Prof. Bjerknes's experiments principally this dissipation in the resonator need be considered, though the sound-waves—if this term be permitted—which emanate from the surfaces at the oscillator may considerably affect the observations made at some distance from the latter. Owing to this dissipation the period of vibration of an air-condenser cannot be accurately determined, and I have already drawn attention to this important fact.

These waves are propagated at right angles from the charged surfaces when their charges are alternated, and dissipation occurs, even if the surfaces are covered with thick and excellent insulation. Assuming that the "charge" imparted to a molecule or atom either by direct contact or inductively is proportinate to the electric density of the surface, the dissipation should be proportinate to the square of the density and to the number of waves per second. The above assumption, it should be stated, does not agree with some observations from which it appears that an atom cannot take but a certain maximum charge ; hence, the charge imparted may be practically independent of the density of the surface, but this is immaterial for the present consideration. This and other points will be decided when accurate quantitative determinations, which are as yet wanting, shall be made. At present it appears certain from experiments with high-frequency currents, and this dissipation of energy from a wire, for instance, is not very far from being proportionate to the frequency of the alternations, and increases very rapidly when the diameter of the wire is made exceedingly small. On the latter point the recently published results of Prof. Ayrton and H. Kilgour on "The Thermal Emissivity of Thin Wires in Air" throw a curious light. Exceedingly thin wires are capable of dissipating a comparatively very great amount of energy by the agitation of the surrounding air, when they are connected to a source of rapidly alternating potential. So in the experiment cited, a thin hot wire is found to be capable of emitting an extraordinarily great amount of heat, especially at elevated temperatures. In the case of a hot wire it must, of course, be assumed that the increased emissivity is due to the more rapid convection, and not, to any appreciable degree, to an increased radiation. Were the latter demonstrated, it would show that a wire, made hot by the application of heat in ordinary ways, behaves in some respects like one the charge of which is rapidly alternated, the dissipation of energy per unit of surface kept at a certain temperature depending on the curvature of the surface. I do not recall any record of experiments intended to demonstrate this, yet this effect, though probably very small, should certainly be looked for.

A number of observations showing the peculiarity of very thin wires were made in the course of my experiments. I noted, for instance, that in the well-known Crookes instrument the mica vanes are repelled with comparatively greater force when the incandescent platinum wire is exceedingly thin. This observation enabled me to produce the spin of such vanes mounted in a vacuum tube when the latter was placed in an alternating electrostatic field. This, however, does not prove anything in regard to radiation, as in a highly exhausted vessel the phenomena are principally due to molecular bombardment or convection.

When I first undertook to produce the incandescence of a wire enclosed in a bulb, by connecting it to only *one* of the terminals of a high tension transformer, I could not succeed for a long time. On one occasion I had mounted in a bulb a thin platinum wire, but my apparatus was not adequate to produce the incandescence. I made other bulbs, reducing the length of the wire to a small fraction ; still, I did not succeed. It then occurred to me that it would be desirable to have the surface of the wire as large as possible, yet the bulk small, and I provided a bulb with an exceedingly thin wire of a bulk about equal to that of the short but much thicker wire. On turning the current on the bulb the wire was instantly fused. A series of subsequent experiments showed that when the diameter of the wire was exceedingly small, considerably more energy would be dissipated per unit surface at all degrees of exhaustion than was to be expected, even on the assumption that the energy given off was in proportion to the square of the electric density. There is likewise evidence which, though not possessing the certainty of an accurate quantitative determination, is nevertheless reliable because it is the result of a great many observations, namely, that with the increase of the density the dissipation is more rapid for thin than for thick wires.

The effects noted in exhausted vessels with high-frequency currents are merely diminished in degree when the air is at ordinary pressure ; but heating and dissipation occurs, as I have demonstrated, under the ordinary atmospheric conditions. Two very thin wires, attached to the terminals of a high-frequency coil are capable of giving off an appreciable amount of energy. When the density is very great, the temperature of the wires may be perceptibly raised, and in such case probably the greater portion of the energy which is dissipated *owing to the presence of a discontinuous medium* is transformed into heat at the surface or in close proximity to the wires. Such heating could not occur in a medium possessing either of the two qualities, namely, perfect incompressibility or perfect elasticity. In fluid insulators, such as oils, though they are far from being perfectly incompressible or elastic to electric displacement, the heating is much smaller because of the continuity of the fluid.

When the electric density of the wire surfaces is small, there is no appreciable local heating ; nevertheless, energy is dissipated in air by waves, which differ from ordinary sound-waves only because the air is electrified. These waves are especially conspicuous when the discharges of a powerful battery are directed through a short and thick metal bar, the number of discharges per second being very small. The experimenter may feel the impact of the air at distances of six feet or more from the bar, especially if he takes the precaution to sprinkle the face or hands with ether. These waves cannot be entirely stopped by the interposition of an insulated metal plate.

Most of the striking phenomena of mechanical displacement, sound, heat and light which have been observed, imply the presence of a medium of a gaseous structure—that is, one consisting of independent carriers capable of free motion.

When a glass plate is placed near a condenser the charge of which is alternated, the plate emits a sound. This sound is due to the rythmical impact of the air against the plate. I have also found that the ringing of a condenser, first noted by Sir William Thomson, is due to the presence of the air between or near the charged surfaces.

When a disruptive discharge coil is immersed in oil contained in a tank, it is observed that the surface of the oil is agitated. This may be thought to be due to the displacements produced in the oil by the changing stresses, but such is not the case. It is the air above the oil which is agitated and causes the motion of the latter; the oil itself would remain at rest. The displacements produced in it by changing electrostatic stresses are insignificant ; to such stresses it may be said to be compressible to but a very small degree. The action of the air is shown in a curious manner, for if a pointed metal bar is taken in the hand and held with the point close to the oil, a hole two inches deep is formed in the oil by the molecules of the air, which are violently projected from the point.

The preceding statements may have a general bearing upon investigations in which currents of high frequency and potential are made use of, but they also have a more direct bearing upon the experiments of Prof. Bjerknes which are here considered, namely, the "skin effect," is increased by the action of the air. Imagine a wire immersed in a medium, the conductivity of which would be some function of the frequency and potential difference, but such that the conductivity increases when either or both of these elements are increased. In such a medium, the higher the frequency and potential difference the greater will be the current which will find its way through the surrounding medium, and the smaller the part which will pass through the central portion of the wire. In the case of a wire immersed in air and traversed by a high-frequency current, the facility with which the energy is dissipated may be considered as the equivalent of the conductivity ; and the analogy would be quite complete, were it not that besides the air another medium is present, the total dissipation being merely modified by the presence of the air to an extent as yet not ascertained. Nevertheless, I have sufficient evidence to draw the conclusion that the results obtained by Prof. Bjerknes are effected by the presence of air in the following manner :—1. The dissipation of energy is more rapid when the resonator is immersed in air than it would be in a practically continuous medium, for instance, oil. 2. The dissipation owing to the presence of air renders the difference between magnetic and non-magnetic metals more striking. The first conclusion follows directly from the preceding remarks ; the second follows from the two facts that the resonator receives always the same amount of energy, independent of the nature of the metal, and that the magnetism of the metal increases the impedance of the circuit. A resonator of magnetic metal behaves virtually as though its circuit were longer. There is a greater potential difference set up per unit of length, although this may not show itself in the deflection of the electrometer owing to the lateral dissipation. The effect of the increased impedance is strikingly illustrated in the two experiments of Prof. Bjerknes when copper is deposited upon an iron wire, and next iron upon a copper wire. Considerable thickness of copper deposit was required in the former experiment, but very little thickness of iron in the latter, as should be expected.

Taking the above views, I believe, that in the experiments of Prof. Bjerknes, which led him to undoubtedly correct conclusions, the air is a factor fully as important, if not more so, than the resistance of the metals.

ON THE TEMPERATURE OF THE ELECTRIC ARC.*

BY J. VIOLLE.

The author states that he experimented under widely different conditions—from 10 amperes and 50 volts up to 400 amperes and 85 volts. Nevertheless, he found the intrinsic brilliancy of the positive carbon identical for all arcs. The measurements taken by the spectrophotometer in various parts of the spectrum, and the photographs taken, left no doubt whatever on this point. It follows from this that the temperature of the arc is constant—that is to say, it is that of the volatilisation of carbon.

The author produced a 400-ampere arc, the end of the positive carbon, after five or six minutes, presenting a white-hot mass for a length of 1cm. Before commencing the experiment, a hollow was effected about 2cm. from the tip of the carbon, and when, owing to the wearing away of the carbon, there only remained a button of the same brilliancy throughout, a blow caused the button to break off and fall into a calorimeter. This consisted of a little cylindrical copper vessel immersed in water. At the bottom of the cylinder there was a graphite disc, and another graphite disc was placed quickly on the top of the carbon button, when it fell into the cylinder. The calorimeter was completely screened from any radiation from the arc. The loss of heat experienced by the button in falling must have been very small, the calorimeter being within 10cm. of the carbons, and owing to the impetus given to it the button traversed this short space filled as it was with the vapour of the arc very quickly.

The author found that the quantity of heat necessary to bring 1 gramme of carbon to the temperature of volatilisation from 0°C. was 1,600 gramme-degrees-centigrade. According to the determinations of Weber and Dewar some 300 calories are required to warm up 1 gramme of graphite from 0°C. to 1,000°C. There is, therefore, a balance of 1,300 calories. Assuming that above 1,000°C. the specific heat of graphite has the theoretical value of 0·52, these 1,300 calories represent 2,500°C., so that *the temperature of volatilisation of carbon works out at* 3,500°C.

In a note to this communication M. Berthelot remarks that M. Violle's experiments are of the utmost importance to chemists and physicists, and he points out that they are in agreement with some experiments carried out some years previously by M Violle and himself on explosive gaseous mixtures, when temperatures of 4,000°C. to 4,500°C. were observed. M. Berthelot points out that the volatilisation of carbon is not a purely physical phenomenon. Carbon in its native state is not comparable in constitution to the elements, such as oxygen, hydrogen, and nitrogen, with which it is associated in gaseous combinations. Carbon in its native state is a polymerised body. To reduce it to a gas in its monomolecular state we must restore the energy absorbed by this process of polymerisation—a chemical phenomenon—and also the energy which is required for the physical reduction of the monomolecular element into vapour. This consideration gives an idea of the great energy with which gaseous carbon intervenes in reactions carried out at high temperatures. A blow-pipe fed by cyanogen and oxygen in the proportions necessary to form oxide of carbon would give rise under constant pressure to a flame having a temperature of about 3,500°C., a temperature which could be surpassed by sudden combinations of the gases operated with in sufficiently large volumes.

ON THE MAGNETIC PROPERTIES OF OXYGEN AT VARIOUS TEMPERATURES.†

BY P. CURIE.

The author states that he has found that the coefficient of magnetisation of oxygen is constant for fields varying from 200 to 1,350 C.G.S. units. He has also verified the fact that by varying the pressure from 5 to 30 atmospheres, the coefficient of specific magnetisation, with reference to the unit of mass, does not sensibly vary. The ratio of the magnetisation coefficients of the same mass of oxygen and water (-145) at 20°C. is $10^6 k_{20} = 115$; the value ($-0{\cdot}79 \times 10^6$) being taken as the coefficient of magnetisation of water, k being the coefficient of specific magnetisation of oxygen.

The author carried out two series of temperature determinations. In one set he used a bulb of ordinary glass filled with oxygen at 5 atmospheres pressure. In the other set he used a bulb of hard glass filled with oxygen at 18 atmospheres pressure. This latter bulb was brought without accident to a temperature of 450°C., the pressure being then 45 atmospheres. It was found that the coefficent of variation of k with temperature increased as the temperature fell. The curve given by the formula—

$$10^6 C\, k_t = \frac{33700}{273+t} = \frac{33700}{T},$$

where t is the temperature, and T the absolute temperature, coincided accurately with the observations of the first series of experiments. The determinations of k in the second series were 1 per cent. to 2 per cent. too high between 200°C. and 350°C.

The law of the variation of k is, therefore, an extremely simple one: *Between 20°C. and 450°C. the coefficient of specific magnetisation of oxygen varies inversely as the absolute temperature.*

The author points out that this result is important to magnetic theory. Oxygen is of all magnetic bodies the most simple in molecular constitution. There is every ground for believing that the complete investigation of the properties of this body will give the clearest ideas as to the nature of magnetic phenomena.

The coefficient for air may be calculated by only taking the oxygen it contains into consideration. We have for the volume coefficient of air at one atmosphere pressure

$$10^6 \chi_t = \frac{2{,}760}{T^2}.$$

This formula may be used as a temperature correction in all magnetic determinations carried out in air, assuming that the composition of air does not vary with the temperature. This coefficient relating to a cubic centimetre of air rapidly decreases as the temperature rises. At 20°C. it makes a 4 per cent. correction necessary in the case of water; at 400°C. its value is five times less.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 6th.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Paper to be read:—"The Theta-Phi Diagram of the Thermo-dynamics of Steam," by J. Macfarlane Gray.

SATURDAY, January 7th.

ROYAL INSTITUTION.

3 p.m. Juvenile Lecture. "Astronomy," by Sir Robert Ball, F.R.S.

TUESDAY, January 10th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion:—"Gas-Power for Electric Lighting," by J. Emerson Dowson, M.Inst.C.E. At this Meeting the Monthly Ballot for members will be taken.

THURSDAY, January 12th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be further discussed:—"Experimental Researches on Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S.

FRIDAY, January 13th.

PHYSICAL SOCIETY.

5 p.m. Paper to be read: "Upon Science Teaching," by F. W. Sanderson, M.A.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read:—"Description of the Design and Construction of a Road-way Bridge over the River Cam," by Edwin Hulme, Stud.Inst.C.E.

SOCIETY OF ARTS.

8 p.m. Howard Lecture I. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

SPECIAL NOTICE.

With this Number is issued Gratis a Tabulated Statement showing the Central Lighting Stations of the United Kingdom in Operation and in Progress.

Next week will be issued (Gratis to Subscribers) a MAP, printed in colours, showing the Streets in the Metropolis in which Mains are actually laid for Private Lighting up to January, 1893, together with the areas allotted to the different Supply Companies. This Map will be similar to those previously issued as Supplements to "The Electrician."

1892.

Year after year, as this planet approaches a particular point in its orbit, civilised mankind proceeds with no little solemnity, and considerable sameness, to take stock of the events of the preceding three hundred and sixty-five days. Column after column is devoted to a chronicle, more or less dull, of the art, politics, coal trade, and what-not of such and such a twelvemonth. The unfailing recurrence of the phenomenon offers a tempting opportunity for the display of a little originality, which may take the shape of allowing the advent of a new year to pass by without the customary stock-taking. There are many customs which are more honoured in the breach than in the observance, but it seems to us that if people can really be induced to read these annual lucubrations, they serve a sufficiently useful purpose to warrant their periodic appearance. A clear idea of leading events is worth having, and it may frequently be gained by digesting some of these extremely hardy annuals.

So far as concerns electrical science, 1892 is remarkable neither for activity nor originality. On the first day of the year, a long life of scientific achievement was gracefully rewarded by the elevation of Sir WILLIAM THOMSON to the peerage; whilst the closing weeks witnessed the termination of the labours of the committee charged, by the Board of Trade, with the supremely important duty of settling the fundamental electrical standards. Appointed in December, 1890, "to consider whether any, and if so, what, steps

We have been unable to obtain detailed information with regard to the following central lighting stations, which, with the exception of the first, are for the most part small ones:—City of London, Bankside and Wool Quay (alt.-cur. trans., sub. sta.); Crystal Palace and District (con.-cur. trans.); Bournemouth (alt.-cur. trans.: 7,500 lights capacity); Bradford (low pressure with batteries: 15,000); Bray (alt.-cur. trans.); Carlow; Chagford (alt.-cur. trans., sub. stat.); Chatham (alt.-cur. trans.); Cambridge (alt. cur. trans: 6,000); Cowpen; Derby (low pressure with batteries: 500); Derby (Town Council); Eastbourne (alt.-cur. trans.); Hull (Town Council); Larne (alt.-cur trans: 4,000); Newcastle (2 stations, alt.-cur. trans); Nelson (Lancs); Thetford (low pressure with batteries: 1,000); Taunton (alt.-cur. trans.: 6,000); Waterford (alt.-cur. trans.: 1000); Weybridge (alt.-cur. trans.: 2,000); Woking (alt.-cur. trans.).

The following stations are **Projected**:—Accrington (low pressure with batteries, Town Council); Bolton (Town Council); Cardiff (Town Council); Heckmondwike (Local Board); Manchester (five-wire, Town Council); Nottingham (three-wire, Town Council); Richmond (low-pressure); Salford (alt. cur trans., Town Council); Whitehaven (Town Council); Wolverhampton (alt.-cur. trans., Town Council); Worcester, (alt.-cur. trans., Town Council).

should be taken for the provision of electrical standards," the committee held several sittings, and examined numerous representative witnesses. Its preliminary report was published in August, 1891, and on November 29th last its final report was signed. Before many more years, we may reasonably hope to see the legislative adoption of the same electrical standards of measurement all over the civilised world, England, America, Germany, and France leading the way. This may seem to some but a very peddling affair. We may, however, perhaps realise its intrinsic importance if we try to imagine the vexation of spirit which would be caused by the simultaneous existence of half-a-dozen different amperes, volts, and ohms; and the lamentable waste of brain tissue which would have been avoided had international standards been possible when European nations first began to think of evolving order out of the chaos of miles, toises, stunden, versts, pounds, livres, pfunde, and funts. In the domain of pure electrical research, the most striking work has been that carried out by Prof. DEWAR, in collaboration with Prof. FLEMING, on the electrical resistance of pure metals, alloys, and non-metals at the boiling point of oxygen, an investigation which showed not only that the specific resistance of perfectly pure metals tends to zero at absolute zero temperature, but revealed a remarkably delicate means of testing the purity of metallic substances. At the British Association, which met in Edinburgh in August, the average of the Papers was even below the not too high standard which obtains at these gatherings. Interesting discussions, however, took place upon the nomenclature of electrical units, and the desirability of establishing a national physical laboratory, a most appropriate subject in view of the presence at the meeting of Prof. VON HELMHOLTZ. The discussion disclosed the existence of a considerable diversity of opinion as to the utility of such an institution, and no two speakers could agree either as to the proper functions of such a national physical laboratory, or as to the expediency of soliciting Government support. Dr. LODGE, who opened the debate, made, it was generally admitted, a powerful and well-reasoned exhortation on behalf of the more scientific organisation of the Grand Army of Science, and for the delegation to a highly equipped central institution of investigations for which amateurs and busy professors have neither the time, the money, nor the apparatus.

At the Institution of Electrical Engineers the 1892 Session was opened by an address on "Electrotechnics" from Prof. AYRTON, an address which, with the exception of a single spirited attack upon "useless Greek," kept commendably clear of the ever-burning question of the relative value of a scientific and of a classical education. As to the speaker's heartfelt conviction on this point, however, there could be but little doubt, and, as we listened to his glowing eulogy of electrotechnics, a passage from an address on popular culture delivered some fifteen years before at Birmingham came irresistibly to mind. "I cannot help thinking," said the speaker on that occasion, "that one of the most narrow, and what will eventually be one of the most impoverishing, characteristics of our day is the excessive supremacy claimed for physical science. This is partly due, no doubt, to a most wholesome reaction against the excessive supremacy that has hitherto been claimed for literature, and held by literature, in our schools and universities. At the same time, it is well to remember that the historic sciences are making strides not unworthy of being compared with those of the physical sciences, and not only is there room for both, but any system is radically wrong which excludes or depresses either to the advantage of the other." Prof. AYRTON's Address was followed by a decidedly sensational experimental lecture by Mr. NIKOLA TESLA in the theatre of the Royal Institution, and later on by the interesting Paper of Messrs. GLADSTONE and HIBBERT, "On the cause of the changes of Electromotive Force in Secondary Batteries," in which they described a variety of experiments tending to prove their contention that it is to variations in the strength of the sulphuric acid that we must look for the main cause of the variations of the electromotive force of secondary batteries. The last paper of the year was a lengthy contribution from Dr. FLEMING, entitled: "Experimental Researches on Alternate Current Transformers," the discussion on which, after extending over two evenings, was adjourned until the 12th of this month. Both the composition of the Council, and the wholesale method of electing associates, have been called into question during the year, and there seems to be a widespread feeling that the quality as well as the quantity of the associates should be taken into consideration by the powers that be. Last, but not least, the year 1892 has seen the compilation of a compendious index to the volumes of the Institution Journal covering the period 1882-1891.

Electric lighting has during the twelvemonth just elapsed continued to progress, but its advance has been uneventful and the pace moderate. In the Metropolis the only new ground broken has been in the City, where the street arc lighting is now practically complete, and where some way has been made with the private lighting mains. The electric lighting business gives every indication of settling down to a prosy and, let us hope, prosperous middle age. New types of dynamos, new systems of distribution are at a discount, and the grim necessity of earning a dividend has concentrated all energies upon the effecting of minute economies and the encouragement of an even load by all manner of ingenious devices. The three-phase craze has died out, and the earthing of the middle wire of a three-wire system has taken its place as an excuse for mild polemics in the papers. Niagara has at last been harnessed, but now that the thing is done—or, rather, nearly done—crabbed critics are saying that the coal-fields of Lancashire, supplemented by a system of electric transmission, are, after all, superior as a source of cheap power to the Horse Shoe Falls. Not the least noteworthy of events has been the way in which the successive tests of Prof. EWING have removed the last doubts which have not unnaturally lingered in the minds of steady-going mechanical engineers as to the economy of the Parsons' turbine at high and low loads. The Crystal Palace Exhibition, which opened on the 9th January with the avowed intention of giving to electric lighting in 1892 an impetus similar to that afforded by the Exhibition of ten years before, resulted in a loss to the Crystal Palace Company and little profit to the electric lighting industry. In America, 1892 will be memorable in the annals of electricity for the amalgamation of the Edison and Thomson-Houston Companies under the name of the General Electric Company, with its natural sequel—a merciless attempt to crush the life out of all less powerful concerns, and thus secure a monopoly of the entire heavy electrical engineering business of the United States.

Municipal enterprise in the direction of electric lighting continues as vigorous as ever. Accrington, Blackpool, Stafford, and Worcester have all voted large sums to carry out municipal electrical supply schemes; the Vestry of Hampstead is determined to emulate the Vestry of St. Pancras, and Brighton has within the last few weeks decided to expend no less than £35,000 in extending its present system. The foundation-stone of a municipal electric lighting station was laid at Portsmouth in October, and just a month before the Dublin Corporation took over the electric light

Hosted by Google

works from the contractors. Finally, Glasgow, after buying up the local company in a straightforward, if not too generous, manner, has also plunged into the fascinating trade of supplying electric energy. As to the local authorities who are "considering the matter," their name is Legion. The immediate disadvantages of "municipalisation" are purely social; meanwhile, until the inevitable results, good or bad, of this propensity begin to mature, electrical contractors may congratulate themselves on the prospect, which the trading mania of municipalities affords, of getting hard cash, and not shares, for work done. Up to the present, municipal management has fulfilled the prophecies neither of friends nor foes.

From the point of view of mileage in operation, electric traction has during 1892 gone perilously near to retrogression. The Side Overhead Trolley system, it is true, commenced work on the very last day of the year, but both at Croydon and at Barking accumulators cars have ceased to run, and at Birmingham they have involved a loss. The Central London Railway is still completely *in futuro*, and the Liverpool Overhead Railway has not, as yet, given us a taste of its quality. On the other side of the account may be set down the increasing receipts and decreasing cost per mile run of the trains on the City and South London Railway, and comfort may possibly be found in the exhilarating spectacle of no less than four important metropolitan electric railway schemes hung up in a state of suspended animation in the Legislature, not to mention one in receipt of the Royal Assent and two new schemes now in the sanguine stage of promotion. On the whole the year's record is not brilliant. The progress of electric traction in this country is undoubtedly slow, and the inactivity is due to the lack of demand by the public for rapid transit and to the reluctance of capitalists to finance it, rather than to any disinclination on the part of contractors to undertake the work.

The telegraph world this year is in the happy position of a country without a history. In submarine telegraphy the most noteworthy incidents have been the continued activity of the French, the laying of the Senegal-Pernambuco cable, and the decision of the Australasian Colonies to revert to a slightly higher tariff, *i.e.*, 4s. 9d. a word in lieu of 4s. In accepting a resolution, moved by Sir E. Birkbeck on April 26th, the Government pledged itself to take immediate steps to telegraphically connect the signal and life-boat stations around our coasts with one another and with the main system of the country, and to appoint a Royal Commission to inquire into the larger question of telegraphically connecting our outlying lighthouses and lightships with the shore. At the time of writing a large sum has already been spent on land-lines, and the Royal Commission, after an exhaustive inquiry, has issued an interim report. In telephony the past twelvemonth has been one of "alarums and excursions." Early in the year the London Chamber of Commerce began to stir, and by the end of March had got itself into an influential deputation, which waited on the Postmaster-General, who thereupon made a speech in the House of Commons announcing the advent of a new era of telephony, which new era subsequently became embodied in a Treasury Minute. The Government proposed to take over the telephone trunk wires from the National Telephone Company, and would in future assist that concern in its endeavours to provide the public with a good service. Apparently, this Arcadian picture was not to the liking of Dr. Cameron, for on March 29th he attempted to cut the telephone tangle by moving a resolution in favour of Government purchase. But the British Public, as represented by Her Majesty's faithful Commons, decided by a large majority to postpone the inevitable. Exactly three months later the New Telephone Company, the *raison d'être* of which had by this time become rather obscure, asked the public to subscribe the balance of the capital not taken up by the National Company. Finally, on December 10th, the lamb lay down with the lion, and the threatened telephone war to the knife passed away in a fizzle of financial Press congratulations. In America, Edison was, on May 3rd, granted a long-deferred patent, covering, it would seem, all telephones in which carbons are used. On October 19th, a more solid achievement was recorded, namely, the inauguration of the New York-Chicago telephone line, which, as the distance separating these two towns is about 1,000 miles, is by far the biggest thing of the kind in the world, so that its progenitors may rest content.

Electrical litigation has, as in former years, been rampant. On February 23rd, the action brought by Mr. Lane Fox against the Kensington and Knightsbridge Electric Lighting Company for alleged infringement of his distribution patent No. 3988 of 1878 came on for hearing before Mr. Justice A. L. Smith, the battle finally ending in the Appeal Court six months later when the patent was invalidated on the grounds of disconformity, insufficiency of description, and want of utility. *Requiescat in pace.* On November 2nd Dr. Hopkinson commenced his action against the St. James and Pall Mall Electric Light Company for infringing his three-wire patent No. 3576 of 1882, and Mr. Justice Romer's decision thereon is still pending. On December 13th the action brought by the National Telephone Company against Mr. Graff-Baker for disturbing the Leeds telephone circuits by the working of his electric cars came on for hearing before Mr. Justice Kekewich, and now stands adjourned until the 12th inst. On April 5th the Brush compound-winding patent No. 2003 of 1878 received its quietus in the House of Lords after a long career of uninterrupted misfortune in the Courts below. In his native land, *per contra*, Mr. Brush's claim to the invention of the pasted accumulator plate has again been sustained, as has Mr. Edison's incandescent lamp patent.

The death-roll of 1892 has been unusually heavy. The National Telephone Company lost its president, Mr. Leyland, at a moment when it could ill spare him, and the New Telephone Company was likewise deprived of its leader, the Duke of Marlborough, at an equally critical juncture; whilst the names of Van Depoele, Slattery, Eugene Cowles, Peter Willans, Edward Graves, Cyrus Field, Frederic Gisborne, and Werner von Siemens recall valuable services rendered to electric traction, distribution, metallurgy and engineering, telegraphy and science.

SELF-INDUCTION IN TELEGRAPHY AND TELEPHONY.

In the course of a very interesting Paper by the late Mr. Willoughby Smith on "The Working of Long Submarine Cables," read before the Society of Telegraph Engineers on February 12, 1879 (*Journal*, Vol. VIII.), after describing certain tests in which self-induction was deliberately introduced with the object of neutralising the capacity of a cable, he remarked:—"From the results of these and similar experiments, I was under the impression that by a judicious distribution of electro-magnets on subterranean lines, greater speed might be obtained." Once or twice since this date, electricians recognising that the great enemy of high-speed telegraphy in cables, or even in long land lines, was the retardation due to the capacity of the circuit, and that the effects of capacity are practically opposite to those of self-induction, have suggested, as Willoughby Smith had done, the use of induction coils for

Hosted by Google

improving the working of such lines. On the other hand, since the presence of self-induction in telegraph instruments has given rise to a retardation of a totally different character, other electricians have resorted to every possible device for reducing this quantity to a minimum, especially in telephony. Mr. Oliver Heaviside has always contended that self-induction was useful rather than inimical to long telephone lines, but as no bad line was ever turned into a good line—as far as we have heard—under his auspices, his views were accepted only by a few students of his writings. He recurs to the subject in the course of his articles on Electromagnetic Theory this week.

Meanwhile, the practical application of self-induction in its *rôle* of a negative capacity has formed the subject of a patent which may turn out to be of considerable importance. Before proceeding to describe the methods by which it is proposed that this invention may be carried out in practice, a popular exposition of the two effects may be found useful by non-mathematical readers. A line having a considerable capacity may be compared to an elastic tube. When a current is sent into the former, or when a stream of water is suddenly forced into the latter, a great rush occurs at first, and this decreases at first rapidly and then gradually, until a steady flow is attained.

The phenomenon of retardation due to capacity is easily understood by the foregoing analogy. The liquid distends the elastic tube at first instead of passing along it. On the other hand, an analogy is to be found between self-induction and inertia; but it should be clearly borne in mind that it is only an analogy, and that to say that an electric current possesses inertia is likely to give rise to most erroneous ideas. A line having considerable self-induction, then, may be compared with a tube in which a liquid of considerable mass is set in motion. A stream of mercury suddenly forced along a tube under a given pressure will start more slowly than a stream of water in the same tube and under the same pressure, owing to the greater inertia of the mercury, but, as in the former analogy, after a certain time the flow will be steady. The one effect is to a large extent the reverse of the other. Analogy, however, ceases when we consider that the self-induction of a circuit depends rather on its shape and the presence of iron—in fact, on the surrounding medium—than on the nature of electricity, or of what we call an electric current.

The attempts which have hitherto been made to combine self-induction with capacity, so that the former, which can be artificially introduced and accurately adjusted, may neutralise the latter, which is inevitable, have been confined to the use of induction coils at ends of the line. Induction coils are in common use on ordinary telephone lines in connection with the transmitters for speaking, but so greatly do they impede the currents that in certain cases it has been customary to cut out the coil at the receiver while listening. The self-induction being either in the wrong place, unnecessary, or altogether out of proportion to the capacity, the improvement by cutting out the coil has strengthened the idea that self-induction is essentially disadvantageous. A moment's consideration will show that the capacity is evenly, or nearly evenly, distributed along a cable, but it is not quite so clear that the introduction of self-induction at the extremities of the line is of little use in cancelling the capacity. This, however, is the case, and the distribution of self-induction *along* a line is the essence of Patent No. 22,304 of 1891, by Prof. S. P. Thompson. The following abstract has been taken from the specification which bears the title "Improvements in Means for Use in or in connection with the Conveyance of Varying Electric Impulses, applicable to Electric Signalling for Telegraphic, Telephonic, or other Purposes":—

As lines and cables whether aërial, subterranean or submarine are now constructed, there is a practical limit to the distance to which signalling is possible with existing instruments: my invention will increase this distance. There is, also, for a line or cable of given length, as at present constructed, a limit to the rapidity at which signals can be transmitted by instruments of a given type: my invention will increase this rapidity of signalling. There is, moreover, for a line or cable of given length, as at present constructed, a limit to the kind of instrument that can be used to signal, high-speed instruments, harmonic telegraphs and telephones not being capable of being used on long cables or on very long lines. For example, the capacity of an Atlantic cable, which is about one-third microfarad per nautical mile, retards telegraphic signals so much that only a few words per minute can be transmitted. The distance to which rapid automatic signals can be sent through cables of this type is but a few score miles. Through very long cables of existing types, telephones, harmonic telegraphs and rapid automatic instruments cannot be used at all. It is known that the cause of the limitations mentioned above as found with cables and long lines of existing type is the presence throughout the length of the cable of electrostatic capacity. Such electrostatic capacity is in general not located at any one point, but is distributed more or less uniformly along the line or circuit. By this invention the effects of this distributed capacity are counter-balanced by applying distributed electro-magnetic induction. The invention consists in dividing the entire line into sections of preferably equal resistance, and between each section inserting an induction device capable of more or less completely neutralising the electrostatic charge of a portion of the line equal to one section. The electrostatic capacity distributed along the cable or line is thus balanced, as it were, in sections, each compensator so introduced into the line or cable exerting a neutralising effect on the capacity of the cable in the adjacent parts. Thus, for example, if a self-induction coil is of sufficient size and power to approximately neutralise the effects of electrostatic capacity of any cable for a distance of five miles on either side from the point where it is inserted, it will be expedient to treat that cable in sections, each of ten miles length, similar self-induction coils being inserted every ten miles along the cable. Self-induction or mutual induction coils for use as compensators should have not only a high time-constant but a high resistance relatively to that of the sections of cable which they are to compensate or connect. The essence of the sectioning of the cable is, that since retardation results from there being a capacity distributed along a great length, one should so modify the system that movements of electricity to effect the charges and discharges of the accumulations in the cable can take place over short lengths of circuit instead of having to flow in and out from the ends up to the places where the charge has accumulated.

The specification goes on to describe various methods of carrying this invention into practice, and, for the most part, relates to cables having two or more conductors. The simplest case consists of the use of a number of compensators arranged in parallel across the two conductors of a cable. These compensators consist of a wire of high resistance coiled round a core of well laminated iron (preferably composed of numerous fine wires insulated by rust or otherwise from each other) joining the two conductors. The coil is, of course (as well as the core), covered with insulated material, and its choking or self-inducing action, if it consists of a sufficient number of turns of the fine wire coiled near together, will cause sufficient resistance to prevent all but an insignificant quantity of the working charge to short circuit. In electric cables the induction coils must be further arranged so as not to form unwieldy enlargements of the cable, and are preferably long and narrow, and with the axes parallel to that of the cable.

The specification contains fourteen illustrations, showing various arrangements of choking coils, or of mutual induction, or transformer coils connected in series, or in parrallel with two or more conductors in a cable.

In some cases it may be practicable to use an uninsulated conductor in the place of one of the wires above referred to, but such an arrangement will usually be greatly inferior to the twin or multiple conductor system in which all the conductors are insulated. But in all cases it is necessary to bear in mind as an essential part of the invention that the compensators must be distributed through the length of the cable so as locally to counteract the effect of the static inductive capacity of the cable which is itself distributed over the whole length of the cable, and that the completeness of the counteraction will depend upon the compensators being sufficiently numerous thus locally to destroy the ill effect of the static induction. In other words, the cable must have compensators at sufficiently short distances to render it possible to practically neutralise, by means of the compensators, the effect of the static induction in the lengths of the cable between the compensators.

SUMMARY OF ELECTRICAL EVENTS FOR 1892.

JANUARY.

The Queen confers a peerage upon Sir William Thomson (Lord Kelvin) (1st).

Death of Sir George Biddell Airy, ex-Astronomer Royal.

Death of Mr. F. R. Leyland, president of the National Telephone Company (4th).

Opening of the Crystal Palace Electrical Exhibition (9th).

The Royal Academy of Science of Turin present Prof. Hertz with the Brescia premium of £500.

Inauguration of street electric lighting in St. Pancras.

Death of Mr. Alexander Watt (15th).

Presidential Address by Prof. Ayrton at the Institution of Electrical Engineers on "Electrotechnics" (28th).

Dividends declared: St. James' and Pall Mall Company, 8½ per cent.; Anglo-American Telegraph Company, 2⅝ per cent.; Hastings and St. Leonards-on-Sea Electric Light Company, 7½ per cent.; Newcastle-upon-Tyne Electric Supply Company, 4 per cent.

FEBRUARY.

Lecture by Mr. Nikola Tesla before the Institution of Electrical Engineers on "Experiments with Alternate Currents of High Potential and High Frequency" (3rd).

Hosted by Google

The Glasgow Corporation finally decide to purchase Messrs. Mavor and Coulson's central station, business, and plant for £15,000.

The Tramways Committee of the Glasgow Town Council publish a statement showing the relative cost of tramway traction by horses, cable, and accumulators.

Publication of the Parliamentary estimates for the construction of the proposed metropolitan tubular electric railways.

Publication of the London County Council's Rules and Regulations affecting the use of the electric light in theatres and other places of entertainment.

Paper read before the Institution of Electrical Engineers by Mr. Alexander Siemens on "Some Experimental Investigations of Alternate Currents" (11th).

The "Sir William Siemens" Electrical Engineering Laboratory at King's College opened by Lord Kelvin (19th).

Mr. Nikola Tesla lectures before the Société Français de Physique and the Société Internationale des Électriciens (19th).

A widespread magnetic disturbance of unusual severity interrupts telegraphic communication all over Europe and the United States (13th-14th).

A special general meeting of the London Chamber of Commerce "to consider the general position of the commercial community in regard to the telephone service of London and the Telephone Bills now before Parliament."

Deputation appointed to wait on the Postmaster-General to "express the view of the Chamber as to the supreme importance of H.M. Government bringing a General Powers Bill into Parliament so as to afford facilities for the development of the telephone" (22nd).

The action for infringement of Patent No. 3,988 of 1878 brought by Mr. Lane Fox against the Kensington and Knightsbridge Electric Lighting Company comes before Mr. Justice A. L. Smith (23rd).

Dividend declared: Newcastle and District Electric Lighting Company, 5 per cent.; India Rubber, Gutta Percha and Telegraph Works Company, 12½ per cent.; Telegraph Construction and Maintenance Company, 20 per cent.; City of Bath Electric Lighting and Engineering Company, 4 per cent.; Keswick Electric Light Company, 3 per cent.

March.

Paper read before the Institution of Electrical Engineers on "Oil as an Insulator," by Prof. D. E. Hughes (10th).

Electric cooking demonstrations at the Crystal Palace Exhibition.

Interesting experimental lecture before the O. S. A. on "The Behaviour of Insulating Materials under the Action of High Potential Differences," by Messrs. H. B. and W. Fox Bourne (11th).

Official announcement that the Belgian Government propose to take over the telephonic system of that country on January 18th, 1893.

Tenders for the arc lighting (6,000 lamps) of the Chicago Exhibition opened. Only one offer, that of the Thomson-Houston Company, at the rate of $38½ per lamp. Tender peremptorily rejected (15th).

Bill placed before the French Chamber of Deputies authorising an expenditure of £160,000 on the telephone system of Paris.

Conclusion of the hearing of the action, "Lane Fox *v.* Kensington and Knightsbridge Electric Lighting Company," after having occupied the attention of the Court for fifteen days (18th).

Death of Mr. Charles J. Van Depoele (18th).

Deputation of the London Chamber of Commerce to the Postmaster-General to state the views of the commercial community on the state of the telephone system of the United Kingdom (21st).

Important speech by the Postmaster-General in the House of Commons announcing new policy on the part of the Post Office in regard to the Telephone Companies (21st).

Paper on "Load Diagrams of Electric Tramways and the Cost of Electric Traction," read before the Institution of Electrical Engineers by Mr. A. Reckenzaun (24th).

Dr. Cameron's motion in favour of the Government purchase of the telephones rejected by 58 votes in a House of 352 (29th).

Judgment given by Mr. Justice A. L. Smith in the Lane Fox *v.* Kensington and Knightsbridge Electric Lighting Company case, invalidating Mr. Lane Fox's distribution patent No. 3988 of 1878 (30th).

Dividends declared: Kensington and Knightsbridge Electric Lighting Company, 2 per cent.; Liverpool Electric Supply Company, 4½ per cent.; Direct Spanish Telegraph Company, 4½ per cent.

April.

Contracts for the arc lighting of the Chicago Exhibition settled on the basis of $20 per light; 5,000 lights to be supplied by the Thomson-Houston, Western Electric, and Standard Electric Companies (2nd).

Nine tenders sent in for furnishing the incandescent lighting of the Chicago Exhibition; some 85,000 lights required (2nd).

Judgment delivered by the House of Lords in the action of "King, Brown, and Co. *v.* Anglo-American Brush Electric Light Corporation." The decisions of the Scotch Courts, invalidating Brush's "compound-winding" patent, No. 2,003 of 1878, upheld (5th).

The Chancellor of the Exchequer announces a large reduction in the Patent Office fees (11th).

Price of the B.T.U. at Bradford reduced from 6d. to 5d.

Increase of the Chicago Exhibition Government grant from £25,000 to £60,000.

Glasgow Police Commissioners decide to erect 106 arc lights in the streets of Glasgow (11th).

Death of Mr. Eugene H. Cowles, one of the inventors of the Cowles electric process for the manufacture of aluminium (21st).

Acceptance by the Government of Sir E. Birkbeck's resolution *re* Coast Communication (26th).

Paper read before the Institution of Electrical Engineers on "The Light of the Electric Arc," by Mr. A. P. Trotter (28th).

Dividends declared: Indo-European Telegraph Company, 6 per cent.; Oriental Telephone Company, 2¼ per cent.; Submarine Cables Trust, 6 per cent.; Western and Brazilian Telegraph Company, 4 per cent.; Metropolitan Electric Supply Company, 2 per cent.; Eastern Extension Telegraph Company, 7 per cent.; Indo-European Telegraph Company, 10 per cent.; Great Northern Telegraph Company, 8·6 per cent.; Western Brazilian Telegraph Company, 4 per cent.

May.

Issue by the United States Patent Office of three telephone patents to Mr. T. A. Edison, apparently covering all telephones in which carbon is used (3rd).

First meeting of the Joint Committee of Lords and Commons appointed to inquire into the metropolitan electric railway schemes (9th).

Issue of a revised tariff by the National Telephone Company at Sheffield, which was subsequently withdrawn, owing to the hostility which it aroused.

Paper read before the Institution of Electrical Engineers, by Messrs. Gladstone and Hibbert, entitled "On the Cause of the Changes of Electromotive Force in Secondary Batteries" (12th).

Formal amalgamation of the Edison and Thomson-Houston Companies, under the title of the General Electric Company.

Report of the Joint Committee of Lords and Commons appointed to inquire into the various metropolitan electric railway schemes. Committee reported that they could see no reason why the schemes should not go forward; that the proposed lines would tend to relieve the streets of passenger traffic; that electricity was a suitable and efficient source of motive power (23rd).

Award of the Albert Medal of the Society of Arts to Mr. T. A. Edison, "in consideration of the distinguished services rendered by him to the progress of electric lighting, telegraphy, and the telephone."

Fatal accident to Mr. W. P. Willans (24th).

Paper on "Electrical Distribution by the Newcastle-on-Tyne Electric Supply Company," read before the Institution of Electrical Engineers by A. W. Heaviside and R. C. Jackson (26th).

Annual General Meeting of the Electrical Trade Section of the London Chamber of Commerce; election of Major Flood Page as Chairman, and of Messrs. Émile Garcke and Alexander Siemens as Vice-Chairmen; appointment of a Special Committee to deal with the telephone and traction question (27th).

Issue of a Treasury Minute setting forth the future policy of the State in regard to the telephones; introduction of a Bill for facilitating the carrying out of this programme.

First meeting of the Select Committee of the House of Commons appointed to consider the Electric Railway Bills (31st).

Dividends declared: Consolidated Telephone, Construction, and Maintenance Company, 3½ per cent.; Reuter's Telegram Company, 5 per cent.

Hosted by Google

JUNE.

Remarkable lecture by Prof. Dewar at the Royal Institution upon the Magnetic Properties of Liquid Oxygen and Air (10th).

The Taunton Town Council decide by 10 votes to 5 to purchase the Taunton Electric Light Company's Works for £9,300.

Strike of telegraphists throughout the Spanish Peninsula.

The action "Lane Fox *v.* the Kensington and Knightsbridge Electric Lighting Company" comes before Appeal Court II. (Lords Justices Lindley, Lopes, and Kay) (27th).

Dividends declared: Electric and General Investment Company, 25 per cent.; Western Counties and South Wales Telephone Company, 1 per cent.; National Telephone Company, 6 per cent.; West African Telegraph Company, 4 per cent.

JULY.

Inauguration of the Tivoli hydro-electric station (4th).

Helmholtz gold medal conferred upon Lord Kelvin.

The Sawyer-Mann "flashing" patent upheld in the States.

Death of Mr. Cyrus Field (12th).

Widespread earth-current disturbances (16th-17th).

Public subscription to the New Telephone Company opened; the National Telephone Company subscribes one-third of the issue (29th).

Issue of a circular letter to the Electrical Trade Section asking the members to co-operate in sending a representative exhibit to Chicago. No response.

The accumulator cars on the Barking-road section of the North Metropolitan Tramway Company's system cease running (28th).

Issue of the London County Council's Bye-laws relating to Overhead Wires (29th).

Dividends declared:—Eastern Telegraph Company, 6½ per cent.; Edison-Swan United Electric Light Company, 7 per cent.; Electrical Power Storage Company, 6 per cent.; African Direct Telegraph Company, 4s. per share; Manchester Edison-Swan Company, 5 per cent.; Sheffield Telephone Exchange and Electric Light Company, 5 per cent.; Direct United States Cable Company, 3½ per cent.; Globe Telegraph and Trust Company, 4⅞ per cent.; Crompton and Company, 7 per cent.

AUGUST.

Opening of the British Association meeting at Edinburgh (3rd).

Judgment in the action "Lane Fox *v.* Kensington and Knightsbridge Electric Lighting Company" given by the Court of Appeal. The decision of Mr. Justice A. L. Smith, invalidating Mr. Lane Fox's patent No. 3,988 of 1878 on the grounds of disconformity between the provisional and final specifications, insufficiency of description and want of utility, upheld (10th).

The operation of the accumulator cars on the Bristol-road section of the Birmingham Central Tramways Company's system during 1891-92 results in a deficit of £1,679; largely due, however, to abnormal circumstances.

Publication by the Board of Trade of a memorandum stating that, until further experience of the behaviour of electricity meters in actual working has been gained, the Department does not propose to grant any certificates (18th).

Death of Mr. Frederic Newton Gisborne, superintendent of the Canadian Government Telegraph Service and one of the earliest pioneers of Atlantic cable promotion (30th).

Trial at Helsby of the "Brain" covered conduit system of electric traction (30th).

Dividends declared: Cuba Submarine Telegraph Company, 8 per cent.

SEPTEMBER.

Offer of a prize of 5,000fr. by Prof. Elihu Thomson for an investigation tending to the development of our knowledge of theoretical electricity.

Death of Dr. Proell, inventor of the well-known cut-off gear.

Board of Trade Report published showing that 24 Electric Lighting Orders were granted and confirmed during the 1892 Session (23rd).

The Dublin Corporation take over the Electric Lighting Works (28th).

Laying of the Senegal-Pernambuco cable.

Dividends declared: Brush Electrical Engineering Company, 6 per cent.

OCTOBER.

Publication in the *Philosophical Magazine* of an important Paper "On the Electrical Resistance of Pure Metals, Alloys, and Non-Metals at the Boiling Point of Oxygen," by Profs. Dewar and Fleming (1st).

The Accrington Town Council sanction the expenditure of £10,000 on an electric lighting scheme (3rd).

The Blackpool Town Council accept tenders to the amount of £18,709 for electrical plant (4th).

The United States Circuit Court of Appeal give judgment in the suit of Brush Electric Company *v.* Electrical Accumulator Company, upholding the Brush claims to the pasted plate for secondary batteries, but on a narrower basis than laid down in the orignal decision of Judge Coxe given on July 23, 1891 (4th).

The Leeds Corporation prolong the agreement with regard to the Roundhay Park Electric Tramway for twelve months.

Mr. Thomas Hodgkins, of Setanket (N.Y.), presents the Royal Institution with £20,000, to be applied in the promotion of scientific research.

A large number of electric traction "franchises" permitting the overhead trolley system granted by the New York Board o Aldermen.

The action brought by the Edison Electric Light Company against the United States Electric Lighting Company for infringement of the Edison incandescent lamp, U.S. patent No. 223,898 of 1880, decided by the United States Circuit Court of Appeals in favour of the Edison patent (4th).

The New York-Chicago telephone trunk wire opened for traffic (19th).

The Brighton Town Council decide to light the sea-front by electricity.

Laying of the foundation-stone of the Portsmouth municipal central lighting station (27th).

Dividends declared: Brazilian Submarine Telegraph Company, 6 per cent., with a bonus of 1s. per share.

NOVEMBER.

Commencement of the action for alleged infringement of the three-wire patent 3,576 of 1882, brought by Dr. John Hopkinson against the St. James' and Pall Mall Electric Light Company (2nd).

Publication of some important tests of the Parsons Steam Turbine by Prof. Ewing; steam consumption, 26·6lb. per E.H.P.H.

Presidential Address to the Junior Engineering Society on "The Cost of Electric Supply," by Dr. John Hopkinson (4th).

Death of Mr. Edward Graves, Engineer-in-Chief to the British Post Office Telegraphs (9th).

Expiry of the Cheesbrough (Sawyer-Mann) "flashing" patent, No. 4,847 of 1878 (28th).

Paper on "Experimental Researches on Alternate-Current Transformers," read before the Institution of Electrical Engineers, by Dr. J. A. Fleming (24th).

Issue of a Supplementary Report by the Board of Trade Electrical Standards Committee (29th).

Dividends declared: Swan United Electric Light Company, 10 per cent.

DECEMBER.

The Brighton Town Council vote £35,000 for extensions of the Municipal electric lighting system (1st).

The Stafford Town Council decide to borrow £20,000 for carrying out an electric lighting scheme (6th).

The Worcester Town Council decide to accept the tender of the Brush Company for £23,000 for the execution of an electric lighting scheme (6th).

Death of Dr. Werner von Siemens (6th).

Amalgamation of the National and New Telephone Companies (10th).

The Nottingham Town Council decide to adopt a low-pressure system with secondary batteries and continuous current transformers (12th).

The Yarmouth Town Council decide to apply for permission to borrow £15,000 for electric lighting purposes.

Opening of the action brought by the National Telephone Company against Mr. Graff Baker for alleged injury to their business by reason of telephonic disturbances caused by the working of his electric cars at Leeds (13th).

County Court decision at Ipswich that an Electricity Supply Company is bound to renew customers' lamps (14th).

Death of Mr. M. M. M. Slattery, inventor of the well-known Slattery Induction System of Electrical Distribution (14th).

The appeal against the decision giving the Edison Company practically the monopoly of the incandescent lamp business in the United States disallowed, with the limiting proviso that lamps must be supplied to would-be buyers.

The Hampstead Vestry decide to spend £25,000 on a central lighting station (16th).

Death of Mr. Thomas Hodgkins, of Setanket, Long Island, U.S.A., recent donor of £20,000 to the Royal Institution.

The Windsor Town Council summons the Windsor and Eton Electric Lighting Company for breaking up the streets without permission. Company fined (19th).

Hosted by Google

The Electric Construction Corporation seek the assistance of the Electric and General Investment Company in obtaining further capital by the issue of £100,000 Six per Cent. Second Mortgage Debenture Bonds.

Woodhouse and Rawson United (Limited) declare a balance loss of £130,000 on the year's undertaking. A committee of consultation appointed. The Directors authorised to raise a sum not exceeding £20,000 on the security of the floating assets of the Company.

Opening of the South Staffordshire Electric Tramway (31st).

THE ELECTRIC RAILWAYS AND TRAMWAYS OF THE UNITED KINGDOM.

Place.	Length.	System.	Worked by.
In Operation—	Miles.		
Bessbrook—Newry..	3¼	Third Rail (Dr. E. Hopkinson)	Bessbrook and Newry Tramway Company.

ELECTRIC LIGHTING NOTICES.

The following is a list, corrected up to date, of the Electric Lighting Notices for 1893. It will be seen that there are 18 notices as against 32 last year. Of these 18 notices, no less than 11, not including the London County Council's scheme for lighting the Embankment, which, being embodied in a Bill, does not come within the purview of the Board of Trade, are given by Local Authorities, who seem more determined than ever to retain their grasp on electrical enterprise.

ELECTRIC LIGHTING NOTICES.

THE METROPOLIS.

Districts.	Names of Applicants.
Hackney	Board of Works.

PUBLIC COMPANIES WOUND UP, DISSOLVED, &c., IN 1892.

The following are amongst the limited liability companies which have been wound up during the past year, the asterisk denoting that the company was wound up by order of the Court :—

Anders, Elliot, and Chetham-Strode.
*Ateliers Hoster de St. Nicolas.
Blackpool Electric Tramway Company (line purchased by the Blackpool Corporation).
Caledonian Telephone Company (business taken over by the National Telephone Company, Limited).
City of We-tminster Electrical Syndicate (business taken over by the Westminster Electric Supply Corporation, Limited).
Collier Audible Telephone Syndicate (business taken over by the Collier-Marr Telephone and Electrical Manufacturing Company, Limited).
Eclipse Electric Lighting Syndicate.
Electric Date and Time Stamp Company.
Electric Tramcar Syndicate.
Electrical Assets Purchase Company.
*Froude-Hurrell Torpedo Company.
Grange Syndicate.
Henley Telegraph and Electric Construction Company.
Improved Galvanising Company.
*International Electric Syndicate.
Kensington Court Electric Lighting Company (business taken over by the Kensington and Knightsbridge Electric Lighting Company, Limited).
Keys' Electric Company (re-organised under the title of the Electrical Company, Limited).
MacMahon's Patent Electric Check System.
Maquay Syndicate.
Mining and General Electric Lamp Company (reconstructed as the Lithanode and General Electric Lamp Company, Limited).
Muir, Mavor and Coulson.
Mutual Telephone Company (business taken over by the New Telephone Company, Limited).
National Telegraph Works Company.
North-Eastern Telephone Company.
Pioneer Telephone Company (absorbed in the New Telephone Company, Limited).
*Poole and White.
Primary Syndicate.
Roper's Electrical Engineering Company.
Sheffield Telephone Exchange and Electric Light Company (business taken over by the National Telephone Company, Limited, and the Sheffield Electric Light Company, Limited).
South Staffordshire Electric Lighting Company.
Thomas Barraclough and Co.
Vaughan-Sherrin Electrical Engineering Company.
Western Counties and South Wales Telephone Company (business taken over by the National Telephone Company, Limited).

Hosted by Google

The following companies have been dissolved or have ceased to exist, in most cases nothing having been done beyond registration, and no business commenced :—

Armstrong's Electric Light and Power Company.
Barry and Cardiff Electric Light and Power Supply.
Bath Electric Light Company.
Bournemouth Electricity Supply Company.
Bradford Mutual Electric Lighting Company.
Durand Electric, Petroleum, and Gas Engine and Manufacturing Company.
Electric Sewage Utilisation and Improvements Company.
Electro-Chemical Syndicate.
Elieson Electric Company.
Hanley Electricity Supply Company.
Johannesberg Electricity Supply Company.
Kidderminster Electric Light and Power Supply.
Morgan's Automatic Electric Signal System Syndicate.
Northern Counties Electric Light and Power Supply.
Regent Portable Electric Lamp and Lighting Company.
Sherrin Electric Power Generator Company.
Sunderland and District Electricity Supply Company.
Universal Electric Light and Power Trust Corporation.
Water Primary Battery Company.

The following changes in nomenclature have been made :—

Crystal Palace District Electric Supply Company, Limited (formerly the Electric Installation and Maintenance Company, Limited).
Islington and General Electric Supply, Limited (formerly the Camberwell and Islington Electric Light and Power Supply, Limited).
St. Luke, Chelsea, Electric Lighting Company, Limited (formerly the New Cadogan and Belgrave Electric Supply Company, Limited).

THE CENTRAL STATION AT MÜLHAUSEN.*

The central station at Mülhausen was designed by Messrs. Siemens and Halske, and was opened in March, 1888. Although small, the station is full of interest, and is a good example of a type much in favour nowadays.

The installation consists of :—

(*a*) Two boilers.
(*b*) Two steam-engines.
(*c*) Two direct-current dynamos coupled direct to the engine.
(*d*) Battery of accumulators.
(*e*) Underground cables.
(*f*) Switchboard.

(*a*) *The Boilers.*—Two Naeyer tubular boilers are used, having each the following proportions :—

Heating surface	2,100sq. ft.
Grate surface	47·4sq. ft.
Number of tubes	144
Length of tubes	13·12ft.
Interior diameter of tubes	3·86in.
Exterior ,, ,,	4·52in.
Weight of water	6·65 tons.
Working pressure	114lb. sq. in.

The boilers are fed by a pump, or by two ejectors, from a tank supplied by the water service mains of the town. The chimney, which is too large for the present boilers, affords ample margin for the extension of the station. It is 115ft. high, inside diameter at base is 6ft. 7¼in., and at the top 4ft. 11in.

(*b*) *The Engines.*—The engines are of the inverted cylinder compound-condensing type with the following principal dimensions :—

Diameter of high-pressure cylinders	15·35in.
,, low-pressure ,,	21·65in.
Stroke	15·75in.
Revolutions per minute	140 to 160
Indicated horse-power at 160 revolutions	180

The governor permits the revolutions to vary between 140 to 160 per minute by the addition of small weights.

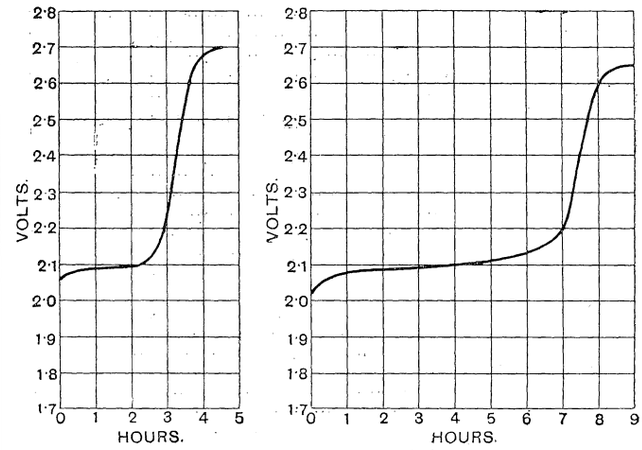
The pipe arrangements are so designed that should an accident occur during working to one of the steam pipes, the engines are not thrown idle, as there are two distinct sets of main steam pipes. Traps are fitted to the main steam pipes just before they enter the engines to insure the use of dry steam as far as possible. The exhaust may be thrown direct into the chimney should the condensers fail. The water for condensing purposes is drawn from a well close to the boilers, and runs to waste after passing through the condensers.

The engines are well and solidly built, and have been free from accident and overheating in the running parts, although they are very compact, and occupy a comparatively small space. Efficiency has, however, not been sacrificed, as during carefully-conducted trials the consumption of water, including cylinder jackets, was only 17·84lb. per indicated horse-power per hour. The cylinders are in two castings, bolted together with liners fitted in each cylinder, and jacketed throughout, except on the bottoms. The high-pressure cylinder is fitted with a piston valve and the low-pressure with an ordinary D slide valve. The cranks are at right angles, and counterbalanced with weights of a complete disc form. The crank shaft carries an overhung fly-wheel at the high-pressure cylinder end, and the dynamo is bolted direct on the bedplate at the low-pressure cylinder end, the shaft being supported beyond the dynamo by a moveable bracket carrying a spherical bearing.

(*c*) *The Dynamos.*—The dynamos are of the Siemens-Halske type, with armature in the form of a ring surrounding the magnets, which are six in number, and bolted direct on to the prolongation of the crank shaft. The armature is bolted direct on to the bedplate of the engine. This arrangement has among others the advantage of reducing to a minimum—

(1) The space occupied.
(2) The staff to look after the machine.
(3) The likelihood of stoppages on account of the means of transmission giving way.
(4) The initial price of the machines and their upkeep.

The brushes are so arranged that they can all be applied or taken off simultaneously by one simple movement, and their position can be altered at will. The periphery of the armature is carefully turned, and acts as commutator. The central rotating magnets produce a powerful magnetic field in close proximity to the armature. This being of a large diameter the circumferential velocity of the field is high, although the number of revolutions per minute is by no means excessive. It is this latter quality which enables the dynamo to be bolted direct on to the engine. Further, the lines of force are very advantageously placed to avoid leakage and so forth, and the difference of potential between two consecutive elements is so small that sparking at the brushes is entirely avoided.



FIGS. 1 and 2.—Tudor Accumulator. Voltage Curves (charging) of a 920 ampere-hour cell. (1) Current kept constant at 230 amperes. (2) Current kept constant at 115 amperes.

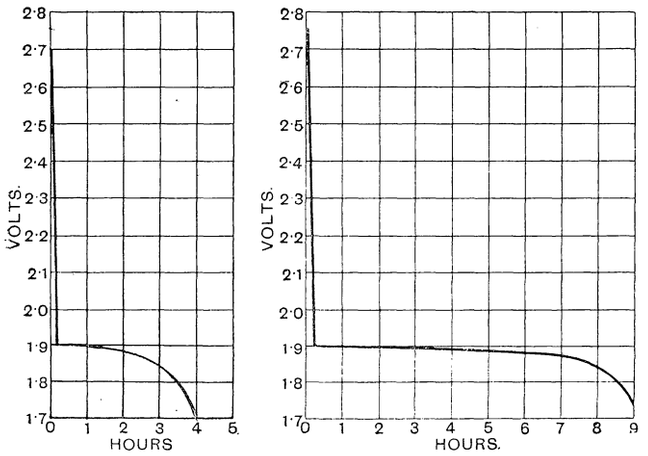
(*d*) *The Accumulators.*—To obtain greater security and economy in working, the station is fitted with three sets of accumulators of the Tudor type. There are two sets with a capacity of 645 ampere-hours, and another set with a capacity of 375 ampere-hours. The three together, giving out 145 E.H.P., during 3½ hours, this, together with the two machines at 180 H.P., gives a total of 505 I.H.P. To show the behaviour of these Tudor cells during charging and discharging we reproduce a curve (Fig. 1) of a cell with a capacity of 920 ampere-hours. The normal current of discharge is 276 amperes, and that of charging 230 amperes. Fig. 1 shows the variation in the pressure, the current being kept constant at 230 amperes during charging, which lasted for 4 hours 25 minutes. In Fig. 2 the charging current is kept constant at 115 amperes, the charging lasting 8 hours 40 minutes. The energy consumed is the same, practically, in both cases, but the pressure when charging with 115 amperes is naturally lower than when charging with 230 amperes. It is especially towards the end, however, that the difference becomes more marked. Fig. 3 shows the discharge with a constant current of 276 amperes, the useful capacity in this case being 920 ampere-hours. Fig. 4 was obtained with a constant discharge of 158 amperes, the useful capacity being 1,320 ampere hours. As the curves show, the volts descend from 2·6 to 1·9 in the first few minutes, and diminish insensibly to 1·83 volts, when they fall suddenly to almost nothing. In practice the pressure should never be allowed to descend below

* Abstract from the *Bulletin de la Société Industrielle de Mulhouse.*

Hosted by Google

1·83 volts. It may be noted that the capacity of a cell augments if the discharge is slow.

(*e*) *The Conductors.*—The cables may be divided into three distinct categories, (*a*) main cables, (*b*) distributing cables, (*c*) branch cables.



FIGS. 3 and 4. Tudor Accumulator. Voltage Curves (Discharge). (3) Current kept constant at 276 amperes (920 ampere-hour cell). (4) Current kept constant at 158 amperes (1,320 ampere hour cell).

The main cables serve to lead the current to the various distributing centres, and the fall in potential in these mains does not exceed 5 volts. The distributing mains distribute the current locally, the loss in this section does not exceed 2 volts, and to these are attached the branch cables that serve the consumers. All the cables are of the Siemens concentric three-wire type. The mains are not run in any special conduits, but are simply buried in the earth at a depth of about 27in. The junction boxes are of cast iron, and filled with an insulating material that solidifies on cooling. The boxes are hermetically sealed with thick oil when closing them down.

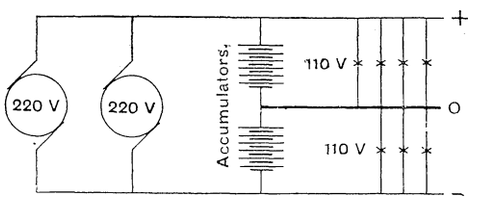


FIG. 5.—The Three-wire system at Mülhausen.

Fig. 5 shows, in a diagrammatic manner, the arrangement adopted in the Mülhausen installation. One of the principal advantages in the three-wire system is the cheapness of the conductors, which may be illustrated as follows :—

Taking first the ordinary two-wire system, let

I = Current in amperes.
L = Distance in metres to be traversed by the current.
T = Drop allowed (in volts).
C = Coefficient depending on the nature of the conductor.
S_1 = Section of one conductor.
S_2 = Total section of the two conductors.

Then $$S_1 = \frac{I L}{T C} \quad : \quad S_2 = 2 S_1 = \frac{2 I L}{T C} \quad . \quad . \quad . \quad . \quad (1)$$

Now, for the three-wire system with the same amount of energy we have double the pressure, and therefore half the current, that is I now becomes I/2 and T becomes 2 T while L and C remain unchanged.

$$\therefore S_1 = \frac{L\, I/2}{2\, T\, C} = \frac{I L}{4 T C}.$$

Since the section of the third conductor may be half the others, and denoting the section in the three-wire system by S_3, we have

$$S_3 = 2{\cdot}5\, S_2 = \frac{2{\cdot}5\, I\, L}{4\, T\, C} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Comparing (1) and (2)

$$\frac{S_2}{S_3} = \frac{\frac{2 I L}{T C}}{\frac{2{\cdot}5\, I L}{4 T C}} = \frac{8}{2{\cdot}5},$$

and $$S_3 = \frac{2{\cdot}5\, S_2}{8} = 0{\cdot}5125\, S_2,$$

which represents an economy of 68 per cent. for the three-wire system over the two-wire system in conductors alone.

The daily output of the Mülhausen central station may be divided into three distinct phases :—

(1) Energy supplied by the accumulators.

(2) Energy supplied by the dynamos and the charging of the accumulators.

(3) Energy supplied by both dynamos and accumulators.

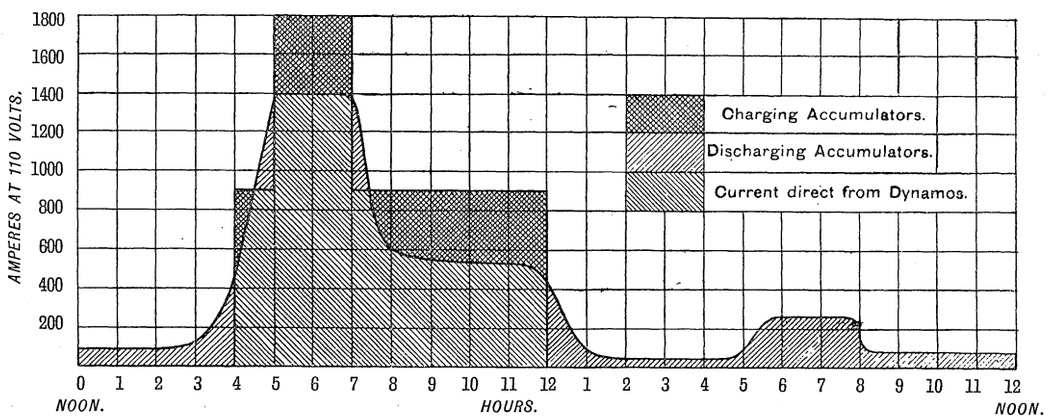

FIG. 6.—Mülhausen Central Station. Output Curve.

Fig. 6 gives the curve of output for a day in December, 1891, and shows that one dynamo alone was working from 4 to 5 and from 7 to midnight, while the two dynamos were at work between 5 and 7, the accumulators supplying the current for the rest of the time.

The advantages of the system are that the accumulators supply the current during the slack hours of the day, the engines only working during the busy hours of the afternoon when the cells are charged, which arrangement enables the engines to be run at their maximum power and efficiency. Further, the accumulators need next to no attention, and this enables the working staff to be greatly reduced, the staff in this particular case being only an engineer, an assistant, and a stoker, the engineer also assisting at any work that may be necessary on the mains.

(*f*) The switchboard is so designed that all the three different conditions above-named can be arranged for.

The price of the current is fixed at 0·96d. per ampere-hour* for lighting purposes, and 0·384d. per ampere-hour for motor purposes, which is equivalent to 0·48d. per 16-c.p. lamp per hour, and 2·59d. per electrical horse-power per hour. Aron meters are used throughout the system.

The actual number of lamps and other appliances supplied with current in July, 1892, were as follows :—7,765 incandescent lamps, 84 arc lamps, 4 1/10-H.P. motors, running ventilators, 13 1-H.P motors, 1 8-H.P. motor, 3 cigar lighters, 1 heating apparatus, 2 installations of portable accumulators for lighting carriages.

* [It appears from Fig. 5, though curiously enough it is not stated elsewhere in the article, that a pressure of 110 volts is used. The price of 0·96d. per ampere hour is equivalent, with 110 volts, to very nearly 8¾d. per kilowatt hour, and 0·384d per ampere hour is equivalent to 3½d.—ED. *E.*]

THE USE OF A SHUNT WITH HIGH SELF-INDUCTION IN CABLE TELEGRAPHY.

A series of experiments have been lately carried out in the German State-Telegraph Office on the effect of the Godfroy system* of shunting the receiving end of a cable with a high self-induction, in order to neutralise capacity effects. The results are worthy of notice, as seen by the figures.

A ring of cable between Hamburg and Berlin was used, 600 kilometres long; resistance, 4,200 ohms; capacity, 150 microfarads; and was worked with Morse instruments and Siemens polarised relays. The coils of the relay, being in parallel, measured about 300 ohms. A large Siemens instrument was used at the receiving end between relay and earth to register the capacity current, and the diagrams are those furnished by this instrument. The battery contained 50 cells. The Fig. 1 shows the capacity current when the word "Berlin" was signalled. A coil of high-resistance (500 ohms) and large self-induction

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

(being sheathed with iron) was then placed as a shunt on each end of the cable. Figs. 3 and 4 show the discharge currents obtained under these circumstances from 50 and 100 cells respectively. It will be noted that in both cases the discharge current is reversed as regards Fig. 1, owing to the high back electromotive force of the shunt-circuit. If this resistance is replaced by one of no self-induction, the discharge is as in Fig. 2, as might be anticipated.

It is obvious that since the reversal of the discharge current can be so effected, it is possible by a suitable adjustment of the self-induction to practically neutralise it. The shunt was therefore made of 250 ohms resistance and smaller self-induction, and a resistance of similar amount but wound non-inductively was added to it, so as to keep the resistance the same as before. The curves (Figs. 5 and 6) show the results obtained with 50 and 100 cells; it will be noticed that the capacity current is practically eliminated.

The high self-induction shunt therefore protects the receiving relay from the effect of the discharge current and therefore also from alterations of magnetic condition, so that the use of a relay is much facilitated.

* For other articles on this and similar devices, see *The Electrician* Vol. XXVI., p. 241, December 26, 1890; also Vol. XXVII., p. 303, July 17, 1891.

THE CABLE STEAMER "GREAT NORTHERN."

This steamer, which is owned by the Eastern and South African Telegraph Company, ran her official trials in Hartlepool Bay recently. The results obtained both on the trial and in the run up to London which followed, were most satisfactory. The "Great Northern" is an iron vessel, built twenty-two years ago by Messrs. Denton, Gray, and Co., and engined by Messrs. Thomas Richardson and Sons, of Hartlepool. When the question recently arose as to new boilers, the ship was found to be in such a good state of preservation that the Company decided to renovate and fit her with the most modern machinery. Messrs. Richardson and Sons obtained the contract for the work, and under the personal superintendence of Mr. P. L. Isaac, the Company's engineer, the ship has been fitted out in a most efficient manner. The old compound engines have been replaced by a set of triple expansion engines of the most approved type, and one single-ended boiler working at a pressure of 160lb. per sq. inch. The diameters of the cylinders are 17in., 28in., and 46in. by 33in. stroke, and although working on three cranks no more space is taken up in the ship than with the old engines. The high-pressure and intermediate-pressure cylinders are steam jacketted and fitted with Morison's circulating receiver, the casings being drained by means of pulsator drain traps. The engine room fittings include Morison's evaporator and feed heater, Edmiston's feed-water filter, Drysdale's centrifugal pump, Worthington's feed pump, and the boiler is fitted with Thompson's circulator. The boiler is fitted with three Morison's suspension furnaces arranged to work with Howden's system of forced draught, the air being supplied by one of Chandler's engines and fans, supplied by Messrs. Bumsted and Chandler, of Hednesford. By employing one boiler only at 160lb. pressure instead of two working at 65lb. each, the side bunkers have been considerably enlarged, and the amount of coal now carried will thus be double that under the old arrangement. A new steam and hand-steering gear, by Messrs. Clarke, Chapman, and Co., has been fitted, and works a new rudder. Very powerful cable engines, by Messrs. Johnson and Phillips, combining separate picking up and paying-out gears have been fitted, the bow gear having three powerful sheaves made of wrought and cast steel to the Company's own design, and similar to those of the Eastern Company's steamers "Chiltern" and "John Pender." A new cable tank has been added aft, making the number four. These tanks are capable of taking 532 knots of deep-sea cable, a large quantity for a vessel that is essentially for cable repairing.

The electric light plant on the "Great Northern" consists of two sets of combined direct-driven dynamos, one for 80 lights and the other for 200 lights of 16 c.p. A 20in. search light of Admiralty pattern has been fitted on the upper bridge. The light-plant and search light have been supplied by Messrs. Clarke, Chapman, and Co., of Gateshead. The deck-houses have been extended so as to give extra room to the testing and chart rooms. The vessel is provided with a 28ft. steam cutter, with compound engines, one of eight recently supplied to vessels of the Eastern and other telegraph companies. The "Great Northern" is thus practically as good as a new vessel, and up to Lloyd's requirements for a new iron vessel of her size and class. The extensive alterations and additions to the ship, including new deck-houses and cabins, have been carried out by Messrs. Irvine and Co., and the whole of the work, both in connection with the hull and machinery, has been supervised by Mr. G. Beckwith, marine engineer to the Company.

CORRESPONDENCE.

EARTHING THE MIDDLE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My letter in *The Electrician* of November 25th last on the Regent Street Fire, and incidently upon earthing electric light mains, appears to have attracted a good deal of notice in your columns and elsewhere. My remarks upon earthing—which referred solely to public supplies upon a large scale, and more particularly to those on a "three-wire system"—were somewhat brief and imperfect; hence a certain amount of misapprehension exists as to the main point of my contention. Mr. J. Sayers, for instance, in his letter deprecating wilful earthing, bases his argument upon the *ideal* of a separate conductor system of wiring, viz., *no earth*, and fails to see that those conditions in the instances I am referring to have no existence in fact. It is not a question of double *versus* single insulation, for we have no double insulation. It is not even a question of permitting "earth," for we are already earthed

Hosted by Google

and hopelessly so. I have known lamps to be lighted and metals fused by means of the leakage in our mains. Shocks to the person have been experienced when incautiously handling portions of the system, and testing instruments have been damaged in consequence of the prevailing "earth."

Tests have occasionally revealed its presence on both sides, but invariably greater on one than on the other; and it is reported that one large supply company, after expending much time and labour in futile attempts to rid their system of this "earth," have given up the task as hopeless.

Under these circumstances, the only question for consideration is, whether it is better to put up with this irregular earthing of our installations through the mains, or adopt some means of controlling and regulating it. Earthing the centre naturally suggests itself as the solution of the difficulty, and although that means deliberately sacrificing one insulated side, it will, at the same time, reduce *two dangerous sides* to one. Whatever complications attend earthing the centre conductor already exist in a magnified degree, and, while wilful earthing cannot make matters worse than they now are, it should relieve us of some of our present troubles.

Let us take a typical case. I inspect an installation off a well-known supply on the three-wire system of distribution, and soon become aware of an earth on a main. Taking a couple of incandescent lamps, and connecting them in series with one pole and a convenient gas pipe, they are lighted brilliantly! This tells me not only that an *outer* is earthed, but that I have 200 as against 100 volts difference of potential to deal with. Now, I know very well that if I could but confine that earth to the middle wire I should reduce that difference of potential by one-half, and as we are now solely concerned with insulation, it is unnecessary to insist upon the advantage of 100 as against 200 volts when safety is the principal factor.

As to the probable effect upon the cable itself, or injury by electrolytic action, I cannot do better than refer your readers to *The Electrician* of November 11th last, in which there is a translation of a letter to the *Elektrotechnische Zeitschrift* by Ph. Seubel giving the results of three years' experience of systematic earthing upon a large scale.

Mr. Chamen's letter is of importance as coming from one connected with a well-known supply company, and I am glad to find myself in accord with him on this important question. At the same time I must take exception to his estimate of the value of cut-outs under the conditions assumed. If fuses act in all cases of leakage to earth, then it matters little whether we are earthed or not, intentionally or otherwise. But the danger we have most to fear is the incipient leak of considerable duration, which, while insufficiently pronounced to reveal itself by blowing the fuse, is, nevertheless, capable of igniting combustible material in its track. It may be urged that wilful earthing would render such faults more serious. Perhaps so, but would it not at the same time enhance the value of our cut-outs?

Mr. Andrews not unnaturally chimes in with his concentric system as the way out of our difficulties. Well, if earthing becomes a necessity, few, I should imagine, will be found to dispute the advantage of having the *live wire* shielded and protected by the harmless outer return; and if *no earth* is a *sine quâ non* of our existing system of wiring, then, surely, that system can be regarded only as a temporary expedient.

In discussing this question of earthing, one is handicapped at the outset with the confusion that exists in certain quarters between *earthing* a system and the use of an *earth return*. *The Review* (Insurance, not Electrical), for instance—whose Editor laughs to scorn the idea of earthing the middle wire—gravely recommends Mr. Human to carefully study the evidence in a legal case now before Mr. Justice Kekewich, in which the sole point at issue is the use, or abuse, of an earth return.

It is not so much the present as the future we have to fear. As houses are added on, so will our difficulties increase, and this varying and shifting drag upon our insulation must tell its tale in the long run.

In advocating systematic earthing I am simply recognising the impossibility of maintaining both sides of a large system of supply free from "earth," and the advisability of effecting a compromise with nature by conceding one pole.—Yours, &c.,

H. Human.

Guardian Fire Office, 11, Lombard-street, E.C.

METHOD OF CHARGING FOR AN ELECTRICITY SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I thank Professor Garnett for pointing out another possibility of my meter system. It must not be lost sight of, however, that it is the short duration of the maximum load that forces electricity supply companies to charge a high price per unit, and that if for any reason the duration of maximum load is increased the price per unit can be decreased. A three days' London fog will enormously swell the receipts of a supply company charging at a uniform rate, but what about the customer when his electricity bill comes in? and how many are deterred from adopting the electric light by what he says about its expense. With a differential charge, electric lighting would often cost less than gas in the case of a long fog, and still bring in a good return to the supply company. It is those consumers who, in ordinary weather, only require current from, say an hour before sunset till 8 o'clock in the evening—that is about 500 hours per annum—who run up both the capital and running expenses of the supply companies.

At these hours I propose that the higher charge should be made. If, through a fog or otherwise, the duration of the heavy load is increased the company's capital expenses are not increased at all and its running expenses very little, while its earnings are very much increased, so that it can well afford to charge at the lower rate. Those customers who only want supply after 8 o'clock at night when the main shop and dressing for dinner load is off, can evidently be supplied at the lower rate with profit to the supply company. Churches, public halls, theatres, &c., will practically come under this head. With the maximum demand arrangement proposed by Profs. Hopkinson and Kennedy and Mr. Wright, these places would be charged so heavily that they would keep to gas in many cases or go in for their own plant.

Then as regards power the system I propose gives the strongest possible incentive to such users as small printers, grinders, cabinet makers, &c., to arrange their work so that they do not use power after the lighting load comes on. Larger manufacturers, who cannot do this, will find it pay them to run their works by electricity from the mains in the summer time only, and use their gas or steam engines in the winter; when they could use their electric motor as a dynamo to do their lighting at the time when supply of current is expensive.

Nearly all manufacturers have engines much too large for them, so as to have ample reserve, they say; this tells very much in favour of electric power, the difference between the efficiency of an electric motor running lightly loaded and a gas or steam engine running lightly loaded being of course immensely in favour of the former. This brings in the question of such places being able to suddenly call upon the supply company for a large current because of a breakdown in their own plant. It is obvious that a building requiring some hundreds of amperes could not be suddenly switched on to the supply mains without seriously interfering with neighbouring supply. This is surely sufficient ground for a supply company refusing to so arrange its connections that this could be done without notice, and more than this, the spirit of the supply clauses in the Provisional Order is certainly against a supply company being bound to keep reserve plant and mains lying idle for any special reason without being paid for it.—Yours, &c.,

W. H. Scott.

SUB-STATION TRANSFORMER SWITCHES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In several recent specifications for alternate-current central stations, transformers for sub-stations have been specified to have changing switches, either automatic or otherwise,

Hosted by Google

to enable the connections of these sub-station transformers to be altered at small loads so as to increase their efficiency. This is generally done by dividing the primary and secondary into two parts which are put in parallel for large loads, and in series for small, the change generally being arranged to occur at about one-fourth or one-third load.

The effect of this is at small loads to increase the copper resistances to four times their original amount. On the other hand the iron losses will be only about one-third of their original amount, as there are double the number of turns in the primary and secondary when the parts are coupled in series; therefore B is one-half, and since the hysteresis varies as $B^{1\cdot6}$ and $\frac{1}{2}^{1\cdot6}$ is very nearly one-third, we will have only one-third of the iron losses.

The question is what increase of efficiency this causes with average load and whether it is commensurable with the extra cost, complication, and risk of breakdown. In order to investigate this I will take as an example a sub-station with the 15-unit Ferranti transformer, of which the losses are given in Dr. Fleming's admirable Paper. In it "The total power taken up in the transformer varies between 210 watts and 525 watts." Therefore the constant iron losses are 210 watts and at full load the copper loss is 315 watts. If the connections of the transformer are changed, as proposed, the iron losses will be reduced to 70 watts.

If we take the average load to be one-tenth of full load, which is about what is generally obtained in central station practice, there are various ways in which the load may come on, which will cause the efficiency to vary slightly. First, we may have one-tenth load on all the time. Here the connections of the transformer will be in series, and to simplify the calculations we will take the losses during ten hours, in which there will be an output of one hour's full load—that is, of 15,000 watt hours. Here we will have a loss in the iron of $10 \times 70 = 700$; and in the copper 126 watt-hours, or a total of 826. The efficiency, therefore, will be $15{,}000/15{,}826 = 94{\cdot}8$ per cent. Secondly, if the change of connections is made at one-third load, we may have just over one-third load for three hours, and no load for the remaining seven hours. During these three hours the coils will be in parallel, and the iron losses will be 630, the copper losses 105, or a total of 735 watt-hours. In the remaining seven hours there will be no appreciable copper loss, but the iron losses will be 490 watt-hours, making a grand total of 1,225 during the 10 hours. The efficiency will be 92·4 per cent. Thirdly, we may have no load for nine hours, and full load for one hour. Here the total loss will be 1,065 watts, and the efficiency 93·4 per cent.

In practice it is the second and third cases or intermediate ones that we have to deal with, and therefore we may say that with this transformer with moveable connections we will have at one-tenth average load an efficiency of about 93 per cent. Now if the connections remain unaltered the whole time, what will be the efficiencies? First, if one-tenth load is on the whole time, the iron loss will be $10 \times 210 = 2{,}100$ watt-hours, and the copper loss will be 31, or a total of 2,131 watt-hours, giving an efficiency of 87·5 per cent. Secondly, if full load is on for one hour and no load for nine hours, the iron losses will be 2,100 as before, but the copper loss will be 315, or a total of 2,415 watt-hours, giving an efficiency of 86·1 per cent. Therefore we may say that with this transformer with fixed connections we will have at one-tenth average load an efficiency of about 87 per cent.

Thus, by having changing connections, we gain at one-tenth average load about 6 per cent. in efficiency. If the average load is less we gain more, if more we gain less, but in central stations one-tenth load is somewhere about the average load on the transformers. The question is, is this 6 per cent. worth the great extra cost, complication, and risk of breakdown? In cases where automatic switches are used there is the risk of their failing to act properly, in which case a serious breakdown may occur; the transformer may be burned out, or if it is protected by fuses they may go, and in any case the light will fail. The same may occur if the switch is worked by hand—a sudden fog comes on when the coils are in series, and either the transformer may be burned out or the fuses go.

Of course, with transformers in which the iron losses are large, such changing switches may be worth using, but with modern transformers of close on 90 per cent. efficiency at one-tenth load the game does not seem to be worth the candle.—Yours, &c.,

GERALD STONEY.

Newcastle-on-Tyne, December 31, 1892.

PARSONS' STEAM TURBINE DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The observations made by Mr. Tesla about my high-speed alternator, in the interesting letter which you published on the 23rd inst., do not call for reply; but there is an incidental remark about Parsons' Steam Turbine which my experience does not at all bear out. Mr. Tesla argues that the steam turbine is not suited for use with continuous-current dynamos, "as the commutators must be a source of some loss and trouble on account of the very great speed." I am sure Mr. Tesla will be glad to know that, in fact, this difficulty does not occur. The exceptionally high speed has not prevented the commutators of the steam turbine dynamos which I have seen from taking a dark polish and running with as complete a freedom from wear and sparking as one observes in the best examples of dynamos driven at ordinary speeds.—Yours, &c.,

Cambridge, Dec. 31, 1892. J. A. EWING.

GILBERTIANA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Thompson has shifted his ground and has taken up a new position, from which he apparently thinks he can throw more mud at Messrs. Wiley and Sons, with safety to himself. He would now have us believe that the epithets he hurled at them referred only to the *manner* in which their American edition of Ruskin was produced, and not, by any means, to the fact that such an edition was produced at all. Probably Prof. Thompson has never seen the edition in question, and knows nothing of its actual merits or demerits; but these have absolutely nothing to do with the matters under discussion, which are his unqualified abuse of Messrs. Wiley and Sons, and his attempt to discredit the translation of Gilbert which they are about to publish. Besides, in his letter of December 30th, Prof. Thompson stultifies himself: he calls Messrs. Wiley and Sons "highwaymen." A highwayman is a robber on the highway, a felon who robs with violence as distinguished from the thief who steals only in sneaking fashion. When the profession was in vogue it mattered little whether the "gentleman of the road" was in broadcloth or in rags; whether he threatened his clients with polite words and a pistol or with oaths and a bludgeon; the robbery was the only point of interest, not the manner in which it was effected. According to Prof. Thompson, Messrs. Wiley and Sons are a "notorious house," a firm who "have earned for themselves an evil notoriety by their pirated editions of Ruskin's works"; they are a "tainted source" and "literary highwaymen." And having thus bespattered a firm of repute Prof. Thompson warns everyone that "the alleged American translation" may well be ignored because of the publishers' imprint it will bear. I am glad Prof. Thompson speaks well of Mr. Mottelay in spite of his effort to boycott his work, for though the forthcoming translation is "an underhand way to an attempt to depreciate the careful work that has been going on for three years by the Editing Committee of the Club," yet Mr. Mottelay is not the "man to lend his name" to it. Again, in his later letter Prof. Thompson still believes Mr. Mottelay "to be an honourable man," and says that "this translation will not make a grain of difference to us." Why, then, does he attempt to cast discredit on it by vilifying the publishers? As to some other points in his letter of December 30th, I am sorry that I cannot explain to Prof. Thompson why Mr. Mottelay did not return to extend his acquaintance, and become enrolled among the members of the Gilbert Club. We are all of us apt to miss the golden opportunities of our lives. Prof. Thompson makes me speak of "astonishing inaccuracies" in my letter

Hosted by Google

published by you on December 23rd; neither word quoted occurs in my letter, either combined or separated. Nor did I suggest directly or indirectly that Mr. Mottelay intended to "pirate" (what a favourite expression!) the Gilbert Club translation, nor that he had ever seen it; and I made no reference whatever to the "big show at Chicago," if by that Prof. Thompson means the Columbian Exposition.

This loose way of making absolutely unfounded statements and baseless accusations throws light on the cause that led Prof. Thompson to try and damage the reputation of Messrs. Wiley and Sons, a cause which he vainly seeks in his last letter to obscure by suggesting entirely new and previously unsuspected reasons.

It will probably be quite unnecessary for me to trouble you again on this matter, as Messrs. Wiley will now have had time to take such steps as they consider desirable.—Yours, &c.,

London, Jan. 3, 1893. JAMES DREDGE.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS ACCEPTED.—On the recommendation of the Electric Lighting Committee, the Derby Corporation has accepted the tender of Mr. Vernon for the building of the electric lighting premises, the amount of the tender being £6,324. 17s. 5d.

CHANGE OF ADDRESS.—Messrs. Slingo and Brooker, electrical engineers, have removed from Solon New-road, Clapham, to 65, Chelsham-road, Clapham, S.W.

MESSRS. CROMPTON AND COMPANY (LIMITED).—The new catalogue and price list of dynamos, generators, and motors manufactured by this firm, has just reached us. Illustrations are given of standard types of the well-known machines manufactured by the Company, including the patent four-pole drum-wound dynamo, combined with a Willans engine of 200 i.-h.-p. Included in the catalogue are notes and data relating to the machines which will be of service to local authorities and other probable users. On examining the prices we find that reductions have been made in almost all cases. Messrs. Crompton have in preparation a complete catalogue of the various manufactures for which the firm is justly celebrated.

CROMPTON-HOWELL ELECTRICAL STORAGE COMPANY (LIMITED).—This firm send us a long list of installations at which Crompton-Howell batteries are in use. The list includes nearly 3,000 cells of various sizes, a large quantity having been sold to the leading electrical manufacturing companies, the Corporations of Glasgow, Hull, and Oldham, the McGill University at Montreal, H.M. dockyards, and to central lighting stations at Oporto, Hove, and Pretoria. The Company has been fortunate during the past year in having had no trouble with regard to renewals or repairs of their batteries.

PORTABLE ELECTRIC LAMPS.—The example set by the London General Omnibus Company, in providing their ticket inspectors with small electric lamps, to enable them to inspect the tickets *en route*, is to be followed by the Liverpool Omnibus Companies. There is also some talk of the metropolitan police being supplied with a small lamp, in place of the old-fashioned bullseye, and several of the railway companies have under consideration the supply of the lamps to their inspectors.

MESSRS. CAMPBELL, MACMASTER, AND CO.—Mr. D. Campbell, of Botolph House, has taken into partnership Mr. Archibald J. Macmaster, and the style of the firm will now be Messrs. Campbell, Macmaster, and Co. The firm are agents for a number of well-known houses in the North of England and Scotland.

MESSRS. PATERSON AND COOPER.—This firm report a fair share of work for the past year. In ship lighting, which is a speciality, plants have been supplied to the Allan Company, the Clyde Shipping Company, the General Steam Navigation Company, the North of Scotland, Orkney and Shetland Steam Navigation Company, to the training ship "Shaftesbury," and to a number of other steamers, and the firm have still in hand plants for the "Polynesian," "Princess Beatrice," and the "Matin." A number of direct driving sets and other ship lighting plant has been supplied to vessels built abroad, as well as to vessels wired by other firms. In installation work Messrs. Paterson and Cooper have been busy, and in the manufacturing department a fair average has been maintained. In measuring instruments the firm have received large orders from abroad, and the output of arc lamps, switch boards, and general electrical apparatus has been well maintained.

ELECTRO-MEDICAL APPARATUS COMPANY.—This Company has now completed its installation at Trafalgar Chambers, W.C. The apparatus and treatment rooms have been fitted with Edison-Swan lamps and with wall plugs for connecting the apparatus when required. A lamp and counterweight with pulley are suspended over the operating chair, and a special lamp is also at hand for the examination or treatment of patients. The managers of the Company have designed a special arrangement with the L. K. current controller, enabling the light circuit, to be used for treatment with safety and convenience. The portion of the current used reaches the patient through the shunt-circuit and can be regulated from 1 to 1,000,000 amperes by means of an adjustable resistance. Another arrangement, which is now complete, is a set of coils of insulators for treatment by Lawrence's modification of Tesla's "Unipolar" method. There is also a bath room, provided with an electric bath and douche, and electro-gymnastic apparatus.

MR. G. WILSON.—This gentleman has recently been consulted with regard to the electric lighting of Ogmore Valley, and has supplied a large portion of the plant required for the installation. The electric light and power business in the neighbourhood of Aberdare has increased to such an extent as to necessitate Mr. Wilson building new premises, and he reports that the outlook for the new year is bright.

MESSRS A. HALL AND CO.—This firm has secured the contract for lighting Nannau Hall, the seat of Mr. J. Vaughan, near Dolgelly, Wales. The generating station is to be about a mile from the mansion, and the motive power will be water. Included in the installation are the parish church parsonage and schools. The same firm have recently concluded the lighting of Dolgelly by electricity, the motive power in this case also being water, the plant consisting of two horizontal turbines of 67 H.P. The electric light has been a success in the district, most of the hotels and shops and many of the private residences being lighted by that illuminant.

MILLING MACHINES.—We have received from Mr. H. F. L. Orcutt a well-illustrated catalogue of Messrs. Ludw. Loewe and Co.'s machine tools and other special machinery, including cutting-off, spindle-centring, and boring machines. Their milling machines are made in great variety; the simpler patterns appear to be well-adapted for jig or quantity work. Several "universal" milling machines are offered, and these are equipped with numerous attachments, adjustments, feeds, and other ingenious devices.

AWARD.—Messrs. Woodhouse and Rawson United (Limited) have received a silver medal for their display of electric light fittings at the Kimberley Exhibition.

CALENDARS FOR 1893.—The Western Union Telegraph Company issue a useful calendar blotting book showing the routes of the Company's cables, and giving a list of the receiving offices in Great Britain.——Messrs. W. H. Willcox and Co. send us a useful date remembrancer, which, in addition to serving as a calendar for the year 1893, gives illustrations of the various specialities of the firm.——Bell's Asbestos Company issue a hanging calendar for the year, which is made the medium for a number of illustrations of the Company's manufacturers.

ACTON.—Skating on the large lake adjoining Captain Ronald Scott's residence at Acton has been much facilitated by the aid of an electric search light, which Captain Scott has placed in a position of vantage, enabling the skaters to proceed with their enjoyment notwithstanding the fog or the darkness of the night.

ARBROATH.—At a cost of over £2,000, Mr. F. C. Fletcher has introduced the electric light at his Letham Grange estate at Arbroath. The installation is extended to the mansion house, stables, riding schools, dairy, and in fact to every building on the estate, with the exception of the small houses for the workmen. A Babcock-Wilcox boiler is used to drive a 12-H.P. engine. The dynamo is of the Victoria compound self-regulating type, and the installation includes 52 L-type E.P.S. cells.

BUXTON.—At the last meeting of the Local Board a short report was read from the Electric Light Committee on the subject of the electric lighting of the town. The Committee reported that they had accepted the offer of a firm to supply an estimate of the cost of an installation for 2,000 lights "free of cost," and it having been decided by the Board to obtain this offer in writing, the further consideration of the matter was postponed. The offer of Messrs. Hammond and Co. to send their representative to lecture on the subject of the electric light was agreed to, and it was further agreed to make a charge of 3d. for the front seats at the lecture in aid of the Free Library!

CAIRO.—The Compagnie Centrale d'Eclairage par le Gaz has signed a contract with the Egyptian Government for an experimental lighting of Cairo by electricity.

Hosted by Google

CAPE TOWN.—The arrangements are now complete for the lighting of Cape Town by electricity. Messrs. Siemens and Halske, who have secured the contract for the plant, machinery, and apparatus, are, we understand, to run the works for twelve months before the Town Council take over any responsibility. The plant will come from Berlin, and it is anticipated that the installation will be complete about the end of 1895.

DOUGLAS, ISLE OF MAN.—A new pleasure resort is to be shortly established in Douglas at Villa Marina, which is to include a large pavilion for dancing and variety entertainments, to be 150ft. long by 60ft. wide. The electric light is to be adopted, and the fittings and decorations are to be on an elaborate scale.

DUBLIN.—At the weekly committee meeting of the Irish Cattle Traders' Association, attention was called to the fact that many of the largest shippers of live stock were greatly inconvenienced owing to the want of facilities for veterinary inspection by the electric light, and the President of the Association informed the Committee that the Privy Council two years ago had given opportunity for veterinary inspection by the electric light, but that only one of the shipping companies had promised to take advantage of this permission. The Committee considered the matter of the greatest importance to the cattle trade, and it was ultimately left over for further consideration.

DUDLEY.—At the last meeting of the Town Council the Clerk reported that applications had been made from Messrs. Siemens Brothers and Co. (Limited) and the Brush Electrical Engineering Company (Limited) to tender for the lighting of the town by electricity.

DUNDALK.—At the last meeting of the Town Commissioners the question of obtaining a renewal of the electric lighting licence, which expires in July next, came up for discussion. The further consideration of the matter was left over till the next meeting.

DUNDEE.—The Harbour Trustees have under consideration the question of introducing the electric light to the docks and harbour, and also the running of electric cars from the West Station to the Cattle Depôt. The trustees' proposal has been remitted to the Urgency Committee for consideration, and this body will shortly report on the question.——It has been finally decided to prepare the necessary specifications for the lighting of the Town Hall and City Chambers by electricity.——The Property Committee of the Council have decided to defer the introduction of the electric light into the Guildhall until the effect of the Town Hall installation has been demonstrated. Altogether, electric lighting business in Dundee is brisk.

EDINBURGH.—A sum of £145 has been paid to the members of the deputation recently appointed to inspect the chief central electric lighting stations throughout the country. This sum includes £20 to the expert who accompanied the deputation.

FALMOUTH.—The Lighting Committee of the Local Authority have received communications in respect to the lighting of the town by the electric light, and this information has been distributed amongst the members of the committee, who will shortly prepare a report on the subject.

FULHAM.—It is announced that a proposal will shortly be made asking the Fulham Vestry to apply for an electric lighting Provisional Order.

HALIFAX.—The *Bradford Observer* states that there is a disposition on the part of the Halifax Corporation to appoint an electrical engineer at a salary of about £200 a year.

MANCHESTER.—Preparations are in progress for lighting the Town Hall at Manchester by electricity. There are at present no less than 3,000 gas burners employed in lighting the building, which consumes about 8,000ft. of gas per annum. The electric current to be supplied will, in addition to the interior lighting, also light the arc lamps on the outside of the building.

RAILWAY STATION AND DEPOT LIGHTING.—The Midland Railway Company, in addition to possessing the record for numerous improvements in railway service, have taken advantage of the recent improvements in electric lighting machinery and apparatus to instal the electric light in all their large stations and goods depôts throughout the country. At Sheffield, where the Company's wicker goods station is undergoing re-modelling, an extensive lighting installation is part of the work.

NELSON.—Mr. James Barton, of Blackburn, has just completed the electric lighting of the Borough of Nelson for the Corporation of that town. This is, we believe, the only Corporation in Lancashire which has itself undertaken the lighting of its district by the electric light.

RATING OF BLAST FURNACES.—The appeal by the Dowlais Iron Company against the assessment of their new furnaces at Cardiff is to be withdrawn, the result of a compromise arrived at at a conference of the Assessment Committee and the representatives of the Company, by which the new assessment is reduced by about 50 per cent.

RUNCORN.—The Board of Commissioners at Runcorn had under discussion yesterday the advisability of introducing the electric light into the public streets of the district.

SALFORD.—The arrangements for the installation of the electric light in the centre portion of the Borough of Salford are being pushed forward, and the plans are now ready.

SHREWSBURY.—The seventh annual industrial exhibition in connection with the Parish of St. Michael's, Shrewsbury, was held last week, and was a great success. At the meeting of the organisers Messrs. Lea, Sons, and Co. were accorded a vote of thanks for the assistance rendered in making the exhibition a success by the installation of the electric light. The firm exhibited a number of examples of hammered metal work.

TAUNTON.—The Board of Trade have granted the electric lighting licence applied for by the Town Council. At the last meeting of the Corporation, the report of Sir T. W. Blomefield and Major P. Cardew, which deals *in extenso* with the objections raised to the licence being granted, and to the views expressed by electrical experts on the subject, was read.

WEDNESBURY.—At the Town Council meeting this week on the question of making additions to the gas lighting of the town, Alderman Williams asked the Council to take into consideration the necessity for introducing the electric light into the district.

WREXHAM.—Further progress in the negotiations between the Town Council and the Wrexham District Electric Supply Company (Limited) is stopped owing to the illness of the Chairman of the Company.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 6, 1892.

22,346. J. D. MILLER. Glasgow. Improvements in telephonic switching apparatus.

22,355. A. GRAY. London. Improvements in the manufacture of electro-printing surfaces.

22,375. W. P. THOMPSON. Liverpool Improvements in the method of welding or working metals electrically. (C. L. Coffin, United States.)

December 7, 1892.

22,422. N. KHEM. Derby. An improved automatic electrical call apparatus principally for use in telephone circuits.

22,473. C. E. L. BROWN. London. Improvements in dynamo-electric machines.

December 8, 1892.

22,534. P. E. SINGER. London. Improvements in musical instruments operated by electricity.

22,589. W. M. MORDEY. London. Improvements in electric switches.

December 9, 1892.

22,615. M. B. FIELD. Glasgow. Improvements in electric current meters.

22,639. H. KROEKER. London. Improvements in glass vessels for accumulators.

22,657. J. G. LORRAIN. London. A new or improved electric accumulator. (M. Dumont, France.)

December 10, 1892.

22,699. P. E. SINGER. London. Improvements in musical instruments actuated by electricity.

22,719. W. GEIPEL. Lambeth. Improvements in street boxes used in the underground distribution of electricity.

December 12, 1892.

22,760. J. A. HEAP. London. Improvements in the method of, and apparatus for, electrolysing aqueous solutions of salts.

22,804. G. J. SPALDING and R. L. HAWKINS. London. Improvements in electric hair and skin brushes.

22,826. W. P. THOMPSON. Liverpool. Improvements in, or relating to, the construction of electric accumulators. (The Suddeutsche Elektricitäts-Gesellschaft, Raab and Bastians, Commandit Gesellschaft, Germany.)

22,837. G. S. HOOKER. London. A combined knocker and electric bell contact.

22,838. C. A. DAY. London. Improvements in long-distance telephones. (C. M. Haynes, United States.)

22,854. H. PIDOT. London. A new or improved electric arc lamp. (P. Archat, France.)

Hosted by Google

December 13, 1892.

22,858. G. DAVENPORT. London. An improved electric arc lamp.
22,889. A. FRITH and G. Y. ASHWELL. Manchester. Improvements in electrical fittings; also applicable to other purposes.
22,914. W. L. WISE. London. Improvements in printing telegraphs. (C. L. Buckingham, United States.)
22,915. W. L. WISE. London. Improvements in printing telegraphs. (C. L. Buckingham, United States.)
22,923. S. Z. DE FERRANTI. Liverpool. Improvements in, or relating to, cables.
22,925. R. H. COURTENAY. London. Improvements in long distance telephonic transmitters of and receivers of sound.
22,931. W. L. WISE. London. Improvements in printing telegraphs. (C. L. Buckingham, United States).
22,947. W. LOWRIE. London. A new or improved method of utilising waste energy in water supply systems for generating electricity.
22,950. R. HADDAN. London. An improved galvanic dry battery or cell, and a composition for use in such cells. (R. Gabarro, Spain.)
22,951. R. E. B. CROMPTON. London. Improvements in switch boards for use in the distribution of electrical energy.
22,958. W. R. GARTON and J. C. DANIELS. London. Improvements in lightning arresters.

December 14, 1892.

22,987. P. M. JUSTICE. London. Improvements in secondary battery plates or elements, and in the process of preparing same. (W. W. Griscom, United States.)
23,007. W. WALKER and F. R. WILKINS. Birmingham. Improvements in galvanic batteries.
23,022. A. GRAHAM. London. An improved loud-speaking telephone.
23,023. T. PUSKAS. London. An improved loud-speaking telephone.
23,039. W. VON WINKLER and J. FEKL. Improvements in electrical connections or means for supplying current to electric motors.

December 15, 1892.

23,051. E. A. MITCHELL and G. T. TUGWELL. Kent. Improvements in galvanic dry cells.
23,054. J. W. DAVIS. Wolverhampton. Improvements in medical and other electric induction cells.
23,057. F. KING and W. P. MENDHAM. Bristol. Improvements in fittings for use in electric light installations.
23,061. W. H. STURGE. Birmingham. Improvements in, or connected with, portable electric lamp fittings.
23,068. A. ROSS, T. WHARMBY, and R. S. HAMPSON. Manchester. Improvements in mechanical and electrical interlocking of railway signals, signal or other levers, and block telegraph instruments, commonly called lock and block.
23,086. R. D. SMILLIE. Glasgow. Improved arrangement for communicating by telephone between several stations.
23,101. C. A. J. H. SCHROEDER and H. E. R. SCHROEDER. London. New primary batteries.
23,113. M. VON DOLIVO-DOBROWOLSKY and the COMPANY ALLGEMEINE ELEKTRICITATS GESELLSCHAFT. London. Apparatus for determining differences between the phases of two electric alternating currents of like number of alternations.

December 16, 1892.

23,158. P. E. SINGER. London. Improvements in electrical meters.
23,159. A. R. G. BEAL. Holyhead. Electro-mechanical depth indicator.
23,185. W. FIELDER and H. NEWMARCH. London. Improvements in, and connected with, alarm clocks and electric sound signalling appliances.
23,218. J. WAGNER. London. An electric mechanism or device for operating valves.
23,231. P. SCHARF. London. Method of effecting in electric glow lamps an air-tight union between entering wires, made of non-precious metal and the glass globe.
23,232. J. Y. JOHNSON. London. Improvements in, and relating to, secondary or storage batteries. (A. M. Michel, France.)

December 17, 1892.

23,269. J. PERRY, M. B. FIELD, and L. J. STEELE. London. Varying price electric supply meter.
23,290. E. ARNOLD. London. Improvements in alternate current motors for single and polyphase electric currents.
23,295. Sir D. L. SALOMONS, Bart. Tunbridge Wells. An improved centrifugal device for opening or closing an electric circuit.
23,314. G. F. COX. Thornton Heath. The automatic electric fire alarm.

December 19, 1892.

23,317. G. HIGTON. Derby. Improvements in thermometers and electrical connections therewith.
23,321. L. B. MILLER and M. W. WOODS. London. Heating liquids by electricity.
23,352. E. D. TAYLOR. London. Improved electrically operated locks.
23,361. A. HEIL. London. Improvements in writing-telegraphic instruments.
23,370. W. F. TAYLOR and P. F. BARNES. Croydon. Improvements in incandescent electric lamps.
23,385. H. W. MILLER. London. Improvements in electricity meters.

December 20, 1892.

23,409. G. A. WASHBURN. London. Improvements in storage batteries.
23,421. B. J. B. MILLS. London. Improvements in sockets for incandescent electric lamps. (J. Hutchinson, United States.)

COMPANIES' MEETINGS.

Gulcher (New) Electric Light and Power Company (Limited).

The fifth ordinary general meeting of this Company was held at Winchester House, E.C., on Thursday, the 22nd ult., Mr. D. de Castro presiding.

The SECRETARY read the notice convening the meeting, and the minutes of the previous meeting, the latter of which were confirmed.

The CHAIRMAN, in the course of his remarks, said that the shareholders had doubtless all received and carefully criticised the report and balance-sheet, and also doubtless expected him to address them in pessimistic terms. On the contrary, however, he rose to address them in the highest spirits, as he considered the position of the Company was never better than at the present time. In the report for 1891 he stated that the whole of the profits resulting from his journey to New Zealand would amount to about £3,000, but in place of this amount he was pleased to say the actual result was £4,800. With regard to the manufacturing account, this showed a loss of £6,000, which fact was, *prima facie*, very depressing, but was not so bad as it looked and was largely the result of the fact that, owing to the Chairman's absence from London, the Company had engaged in unprofitable work. He ascribed this chiefly to the fact that they were only now in a position to produce a dynamo cheap enough to compete in the open market. Their machines were good, but were costly and had not been a manufacturing success, the result being that they had accumulated a heavy stock of these good machines, which they hoped eventually to dispose of. The Directors had accordingly depreciated the value of the stock by more than £2,000, thus reducing the actual manufacturing loss to about £4,000. A portion of this sum was due to the writing down of the value of the lease of their factory, which had arrived at within an appreciable distance of its termination; therefore, more than £3,000 of the £5,000 carried over from profit and loss account was due to the above exceptional circumstances. He would now tell them why he felt more hopeful for the future. By a rearrangement of their managerial staff, resulting in an improved organisation, they expected a saving of £500 per annum, which was a considerable item. The Directors had agreed to waive £500 of the annual fees hitherto paid to them, and this latter reduction would take effect as from June 30th last. They had secured a contract in New Zealand exceeding the amount of the whole of the business hitherto done in any preceding year, and from that contract he expected to make a substantial profit—sufficient, in fact, to wipe out the larger portion of their last year's loss. The Directors had arrived at the conclusion that it was most advisable for the Company to devote itself to the manufacture of central station plant. He was pleased to say that a friend had recommended the tender of the Gülcher Company for a large central station, and that the Directors anticipated securing the contract. The result of their Genoese business had been that the Gülcher dynamos had completely distanced the German machines put down to work against them.

Elmore's Copper Depositing Company (Limited).

The third annual ordinary general meeting of this Company was held on the 30th inst., at the Great Northern Railway Hotel, Leeds, Mr. J. Jepson Atkinson presiding.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, said that a word of explanation was necessary as to why they were holding their general meeting this year at Leeds, rather than in London, where these meetings had hitherto been held. Some shareholders had thought that they had adopted that locale in order to avoid meeting the members of the Company; but he need hardly say that that was certainly not the case, as they had, he thought, approximately, as many shareholders in the north as in the south. But in Leeds the Board wished to emphasise the fact that the Company was a Leeds industry; that its offices were at Leeds; and that the Board meetings were, and had been for some time, held at the works, in order that the Directors might be personally and immediately conversant with what was being done. Therefore, it was only appropriate that their general meetings should be held there, so that their shareholders might have an opportunity of seeing their property and works, and of forming an opinion for themselves of their position and prospects. As they were aware, the accounts submitted to the meeting were for the year ended June 30th last—a period which, as mentioned in the report, was chiefly occupied in completing the machinery and plant. The last six months of that period were disappointing to himself, as well as the rest of them, everyone having sincerely thought that every difficulty was overcome at the end of 1891, when the shareholders last met. However, he frankly admitted that he shared the meeting's disappointment in regard to the working of the Company for the period in question, but he wished to point out what appeared to him to be a very satisfactory feature in the accounts, namely, that they showed a profit derived from the Company's trading to the extent of nearly £800, notwithstanding that the output for the whole year under consideration did not reach more than 5 per cent. of what the plant was laid down to turn out. They might, therefore, easily calculate that if so small an output brought in so large a profit as that, after meeting the whole expenses properly chargeable to the trading account, then, with an output of 15 to 20 tons a week, a much larger profit would result, and it was in these, the most productive sources, from which they anticipated large orders and large profits, such as the manufacture of steam-pipes, that had not yet been entered upon by the Company, although they were taking immediate steps to accept orders for those, and the meeting might take it from him that their steam-pipes, in point of satisfaction to their customers and profit to the Company, would leave nothing to be desired. The Directors had taken no fees since the Company was reconstructed, and would not do so until the shareholders had received a dividend. He wished very strongly to impress upon the shareholders that, notwithstanding the many vexatious difficulties which they had had to overcome, and the long delay in realising some of their anticipations, yet the Elmore process, as an electro-metallurgical operation, was perfectly successful. They continued to receive a large number of repeat orders, and their customers were perfectly satisfied with their deliveries; and they must not for one moment think that the process was a failure, as they were perfectly certain that, in the course of the coming year, they could prove every statement they had made as to its success. In palliation of the Company's difficulties, the Chairman said he would like to refer shareholders to such companies as the Bessemer Steel Company, Bruner, Mond, and Co., the Crecender Tube Company, and others which at present were a great success, but which, in the early stages of their development, presented the same grounds for disappointment as the Elmore Company at present did. Nevertheless, they ultimately achieved remarkable success by dint of hard work and perseverance, and the Company, having a perfectly sound monopoly in their hands, were determined, by the same means, to secure a similar success, and their confidence in this respect could not be better seen than by an inspection of the shareholders registers, which would show that the Directors and officials of the Company and their immediate friends held a very large proportion of the Company's share capital. Since the reconstruction, on June 30th last, two practical commercial gentlemen had joined the Board, and one of them, after investigating the process, had invested something like £20,000 in the concern. These gentlemen were now present, and they meant to work and make the concern a success. He (the Chairman) had done all the dirty work of the Company, and had had all the anxiety and trouble from the beginning; but he had stuck to his shares, and he meant to continue to do so. He believed there was no question about the prices they could get for the work. The only thing was that there had been delay, and on this subject he hoped shareholders would question Mr. Elmore before the close of the meeting. He hoped that in a very short time they would thank him for sticking to the concern. He concluded by formally moving the adoption of the report and accounts.

Mr. W. GOODE JOHNSON seconded the motion.

Mr. HAWKYARD thought that the fact that one of the Directors had invested £20,000, after due investigation, showed confidence in the concern.

Mr. SQUIRE, a London shareholder, observed that last year shareholders hoped for a dividend, and were shown a copper pipe. This year again they hoped for a dividend, and were shown some copper pots.

The CHAIRMAN: These will produce the dividend.

Mr. SQUIRE said he could not help thinking the Directors were easily satisfied. Practically, instead of making a profit, they had made a loss.

The CHAIRMAN: That is on only 50 tons.

Mr. SQUIRE, further alluding to the suggestion that the mechanical part of the principle would not work, complained of the want of details supplied to the shareholders, and said he thought the time had arrived when they should be taken into confidence, and told exactly what the prospects were likely to be. He proposed an amendment—

"*That a small committee of shareholders should be appointed to look into the condition and prospects of the Company, and report to a meeting to be held that day two months.*"

Mr. PRITCHARD seconded the amendment.

A SHAREHOLDER thought it perfectly absurd that so much money should have been swallowed up to produce £700 trading profit.

Mr. W. G. JOHNSON said that, as a new Director, he was not responsible for the past promises, and he did not intend to be. Some shareholders had already had a large dividend; but if he had been a member of the Board that dividend would not have been declared: he should have used it for working capital and completing the plant, which had not been completed to this day. The concern has never had a chance yet. No one has declared it a failure. If vigorously worked, it can do all that is claimed for it, and more. With regard to Mr. Elmore, continued Mr. Johnson, that gentleman was singularly sanguine. He did not think that Mr. Elmore ever made any promises or anything which he did not thoroughly believe in.

Mr. HAYS appealed to Mr. Squire to withdraw his amendment. They had, he maintained, an excellent Committee in Messrs. Johnson and Hooley. So far, these gentlemen were satisfied, and had backed their opinion by putting money into the concern. Hitherto the payment of dividends was a monstrous mistake. The money ought to have been husbanded, and applied for completion of the plant. Unfortunately, there had been in London an element which, for his part, he had always viewed with disfavour.

Mr. HOOLEY observed that their plant was calculated to turn out 20 tons per week, and if they could secure this amount of employment for the plant, a handsome profit would result.

Mr. SQUIRE said that after the appeal that had been made to him he would consent to withdraw the amendment on one condition, that he should be allowed to make an investigation on his own account.

With the consent of the seconder of the amendment, it was unanimously agreed that it should be withdrawn.

Mr. ELMORE, jun., replying to a statement that the Company's land had been flooded, pointed out that there was no land in the neighbourhood of Leeds that had not been so flooded, the flood experienced during the past year being the greatest known for thirty years. With regard to the mechanical difficulties that had been referred to, it was easy to understand that machinery might be required, and could not be procured because capital was not forthcoming to justify the expenditure.

Mr. HOOLEY repeated that, at the end of six months, he would be able to make a satisfactory report to the shareholders. He had more money in the concern than many shareholders that complained. What they had really been suffering from in the past had been want of capital.

The report and accounts were adopted, and Mr. J. T. Cooper and Mr. William Elmore, retiring directors, were re-elected, as were the auditors, Messrs. Price, Waterhouse and Co.

Elmore's Wire Manufacturing Company (Limited).

The second annual ordinary meeting of the shareholders of this Company was held after the close of the above meeting, and was also presided over by Mr. J. Jepson Atkinson. It was of a formal character.

The CHAIRMAN formally moved the adoption of the Directors' report and accounts, which was seconded by Mr. Hays.

A SHAREHOLDER said he would like to know when the wire works were to be in operation.

The CHAIRMAN explained that fairly good progress had been made, and that in all probability the wire works would be in full working order in a week's time.

Another SHAREHOLDER observed that he thought it had been understood that there were orders in hand as far back as two years ago.

The CHAIRMAN: So we had.

SHAREHOLDER: Then why were they not executed?

Mr. HAYS: Because we had not sufficient money.

Mr. JOHNSON: What applied to the former company applies equally to this—it was largely in want of funds.

The CHAIRMAN, in reply to a question from a shareholder, said that it was calculated that the works would produce from 30 to 40 tons. The plant laid down was contemplated to produce 35 tons. He had every possible reason to believe that the initial difficulties having been overcome, and that the Wire Company, like the Copper Company, would more than realise all that had been predicted of it.

The report and accounts were adopted.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322 *&c., &c.*]

COMPAGNIE D'ECLAIRAGE ELECTRIQUE DU SECTEUR DE LA RIVE GAUCHE DE PARIS.—Under this title a Company has been formed by M. Naze at Paris for the exploitation of the concession granted him for the electric lighting of the left bank of the Seine, comprising the 5th, 6th, 7th, 13th and 14th, and portions of the 4th and 15th arrondissements. The capital of the Company is 8 million francs, divided into 16,000 shares of 500 francs each

Hosted by Google

DALZIEL'S ATLANTIC TELEGRAM COMPANY (LIMITED).—This Company was registered on December 29th with a capital of £25,000 in 250 shares of £100 each. The objects are: to carry on the business of agents for any telegraph or cable company, for the collection, transmission and delivery of telegraphic messages of a private or commercial character, for which the full tariff charges or rates have been paid and which are not intended for publication in newspapers or journals of any description, or for public or private circulation in any manner; to construct, improve, maintain or aid in, or subscribe towards the construction, maintenance and improvement of any buildings, telegraph or telephone lines or cables and works of all kinds which may be necessary or convenient for the purposes of the Company; and to accept, purchase, hold and sell shares or stock in any company or undertaking, any of whose objects are similar to, or connected in any way with, any of the objects of this Company, or such as may be calculated to promote or advance the interests of the Company. The first Directors are Davison Dalziel, W. C. Hallett, H. V. Huggins, H. F. Jackson and Major John E. Jameson.

J. E. HOPKINSON AND CO. (LIMITED).—This Company has been registered with a capital of £20,000 in £1 shares, to take over the business of J. E. Hopkinson and Co., at 15, Walbrook, London, E.C., as manufacturers of and dealers in india-rubber, gutta-percha, asbestos, caoutchouc, substitutes for india-rubber, &c.

A. RANSOME AND CO. (LIMITED).—This Company was registered on December 28, 1892, with a capital of £59,000 in £10 shares, to carry on at the Stanley Works, King's-road, Chelsea, S.W., and at the Battersea Works, the business of mechanical and electrical engineers, tool makers, brass founders, metal workers, boiler makers, machinists, metallurgists, electricians, &c.

NEW JERSEY METAL REFINING WORKS (LIMITED).—This Company was registered on December 29, 1892, with a capital of £50,000 in £10 shares, to carry on the business of metal extractors, smelters, refiners, chemical manufacturers, &c., carried on by a Company called the New Jersey Extraction Works (Limited), U.S.A.

ROGER DAWSON (LIMITED).—This Company was registered on the 3rd inst., with a capital of £15,000, in £1 shares. The objects are to acquire by purchase from Alfred Roger Dawson the business of an electric light engineer and contractor, until recently carried on by him in partnership with Alwyn Rashleigh Phipps, under the style or firm of Rashleigh, Phipps and Dawson, and now carried on by A. Roger Dawson alone, as sole owner thereof; with a view to such acquisition, to enter into and carry into effect an agreement expressed to be made between A. Roger Dawson of the first part, Arthur R. Cobbett of the second part, Charles E. Tomlin of the third part, John H. Jenks of the fourth part, and the above-named Company of the fifth part, to carry on the business of civil, mechanical, and electrical engineers and contractors, coppersmiths, brass-workers, braziers, platina-smiths, metal founders, general metal workers, &c.; to contract for the lighting of any public or private place or property by the electric or other light; to establish centres from which light, heat, or power may be distributed; to acquire the right to manufacture or use and put up telephones, telegraphs, phonographs, and all electrical apparatus now known or that may be invented, including all wires or appliances, for connecting electrical or other apparatus at a distance with other electrical or other apparatus, and including the formation of electrical or other exchanges or centres; and to carry on any business connected with the supply of electric light, heat, or motive power, or with telegraphic or telephonic communication, or any other business that may be conducive to the interests of the Company. The subscribers are:—

	Shares.
Alfred R. Dawson, St. Margaret's, Weybridge, Surrey, electrical engineer	1
A. Rathbone Cobbett, Woburn Chase, Addlestone, Surrey	1
Charles E. Tomlin, Kingsdown, Streatham Park, Surrey	1
Frederic H. P. Berlyn, Elm House, Brixton-road, Brixton, London, S.W., electrical engineer	1
Percy J. Dawson, Palace-road, Streatham Hill, Surrey	1
Arthur Hicks, Palace-road, Streatham Hill, Surrey, civil engineer	1
Neville Hicks, Oakfield, Streatham Hill, Surrey	1

TRIPLE-GRIP PULLEY AND POWER SAVING APPLIANCES COMPANY (LIMITED).—This Company has been registered with a capital of £5,000 in £1 shares, to acquire an invention patented by C. T. J. Vautin, relating to an improved fibre pulley, or rim, for covering the periphery of pulleys.

CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—The statutory return of this Company, made up to September 28, 1892, has been filed; 1,631 shares, of a total of £50,000 in £10 shares, have been taken up, and £6 per share called, resulting in the payment of £6,822, leaving £2,964 in arrears.

CARBON ELECTRIC (LIMITED).—The statutory return of this Company, made up to November 25, 1891, was filed on December 29, 1892. The Company was registered on April 15, 1891, with a capital of £20,000, divided into 3,000 preference and 1,000 deferred shares of £5 each, to carry on the business of manufacturers of carbon rods and plates for electrical purposes, carried on by H. J. Chappell at his works in Devonshire. The capital has since been changed to £20,000, divided into 2,100 preference and 1,900 deferred shares of £5 each. At the time of making up, seven shares were taken up, no calls having been made. The first annual return, made up to November 25, 1892, and filed on December 29, 1892, discloses the same state of things, the original signatories to the Memorandum of Association being the only shareholders.

CANTERBURY ELECTRICITY SUPPLY COMPANY (LIMITED).
CARDIFF ELECTRICITY SUPPLY COMPANY (LIMITED).
LOUGHBOROUGH ELECTRICITY SUPPLY COMPANY (LIMITED).
MANCHESTER ELECTRICITY SUPPLY COMPANY (LIMITED).
PENZANCE ELECTRICITY SUPPLY COMPANY (LIMITED).
WESTON-SUPER-MARE ELECTRICITY SUPPLY COMPANY (LIMITED).
WEYMOUTH ELECTRICITY SUPPLY COMPANY (LIMITED).

With reference to the above-named Companies (each of which has a capital of £100 in £1 shares), the Brush Electrical Engineering Company (Limited) states, in reply to circulars from the Registration Office, that these Companies were registered in order that application might be made in the name of local companies for Provisional Electric Lighting Orders in the various towns. It goes on to say that, "although these applications were unsuccessful, and the Companies cannot, strictly speaking, be said to be carrying on business at the present time, we are nevertheless in negotiation with the corporations of the various towns, which may ultimately result in our undertaking, through local companies, the establishment of central electric lighting stations, and in this event the Companies in question would be made use of. In view of these negotiations, therefore, and pending their settlement, we would prefer to keep the Companies alive for the present."

CHAGFORD AND DEVON ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to May 1, 1892, has been filed. The Company was registered on November 18, 1890; 724 shares were taken up at the time of the making up, of which 400 were issued as fully paid. Upon the remaining shares the full amounts have been called, and all calls paid.

CHARLES CHURCHILL AND COMPANY (LIMITED).—The annual return of this Company, made up to December 13, 1892, has been filed. The Company was registered on October 21, 1889, with a capital of £6,000, divided into 140 preference shares of £25 each and 50 ordinary shares of £50. At the time of making up 103 preference and 40 ordinary shares were taken up, of which 50 preference and 40 ordinary shares were issued as fully paid. Upon the remaining 53 preference shares the full amounts have been called, resulting in the payment of £1,325.

CROSSLEY TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to October 6, 1892, has been filed. The Company was registered on July 11, 1884, with a capital of £100,000, divided into 5,000 "A" shares, 12,500 "B" shares, and 2,500 "C" shares of £5 each, to carry on the business carried on by the late Louis J. Crossley, John F. Harrison and Walter Emmott under the style of "The Crossley Telephone Company," and to carry on the business of a telegraph, telephone and electric lighting, heating and motive power supplying and generating company in all or any of their respective branches, and also of a general electric apparatus construction and maintenance company. At the time of making up, 607 "A," 120 "B," and 350 "C" shares were taken up. The full amounts called and all calls (£5,385) paid.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return of this Company, made up to December 5, 1892, has been filed; 1,667 shares, of £5 each, of a total of £40,000, in £5 shares, have been taken up and £4 per share called. The calls paid (including £101 payment in full) amount to £6,645, and £124 remains unpaid. Amongst the principal subscribers are Messrs Crompton and Co. (Limited), and W. T. Henley's Telegraph Works Company (Limited).

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 1st were £966, as against £878 for the corresponding period of last year, being an increase of £88. The total receipts for half-year amount to £22,550, against £20,335 in the corresponding period of 1891, being an increase of £2,215.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of December were £2,092, against £2,180 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December amounted to £59,776 and to £55,830 in the corresponding period of last year, an increase of £3,946.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December, 1892, amounted to £42,295, and to £38,898 in the corresponding period of 1891, or an increase of £3,397.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for December amounted to £20,800, and from January 1st to December 31st to £266,400. In the corresponding months of 1891 and 1890 the amounts were £282,600 and £280,000 respectively.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to allow the vendors' shares, Nos. 8 to 141, to be quoted in the official list.

SOCIETE ELECTRO-MECANIQUE.—The capital of this recently-founded Parisian Company has been raised from 300,000 frs. to 1,000,000 frs., divided into 2,000 shares of 500 frs. each, of which 300, fully paid, have been allotted to the Compagnie Continentale Edison, and 300 to the Société Weyher at Richemond and the Société Jean-Jacques Heilmann et Cie.

SOCIETE FRANCAISE DES TELEGRAPHES SOUS-MARINS.—At a recent meeting of this Company in Paris, MM. Léauté, Lefaivre, Vidal, Contre-

Hosted by Google

Amiral Caubet, and Ronget were elected Directors in the place of MM. J. Lair, E. Clerc, J. Kulp, E. May, A. Sienkiewicz, A. Vuigneer, R. Wallut and P. Wallerstein.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Dec. 30, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,252.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended December 31st were £2,708, as compared with £2,371 for the corresponding period of last year.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square, MANCHESTER.

TO ELECTRICAL ENGINEERS.

TENDERS WANTED.

ELECTRICAL ENGINEERS are invited to TENDER for an INSTALLATION of WIRING AND FITTINGS FOR THE ELECTRIC LIGHT (about 80 lamps) in a private house in the suburbs of London. Specification can be inspected, and copies supplied with orders to view, by application to M. G. Dary, 19, Dashwood House, Old Broad-street, E.C., to whom Tenders should be delivered not later than SATURDAY, January 21st inst.

Advertiser does not pledge himself to accept the lowest or any tender, nor to pay any expenses therefor.

SPECIAL LECTURES.—A COURSE of TWELVE PRACTICAL LECTURES on "PRIME MOVERS FOR ELECTRICAL ENGINEERING" will be given by Mr. E. TREMLETT CARTER, at the SCHOOL OF ELECTRICAL ENGINEERING, 12, Prince's-street, Hanover-square, W., on TUESDAYS and THURSDAYS, from 6 to 7·30 p.m., commencing Tuesday, January 17th. Fee for the Course, £3. 3s.—Apply by letter, or personally, to Lecturer, at the above address.

SITUATIONS VACANT AND WANTED, &c.

COUNTY BOROUGH OF HALIFAX.

WANTED an ELECTRICAL ENGINEER. Salary £200 per annum. Candidates must be capable of advising the Corporation upon the Lighting of the Borough from a Central Station and of managing the necessary proposed works. Applications, enclosing not more than three testimonials of recent date, to be sent to me not later than Thursday, the 26th January.

By order,
KEIGHLEY WALTON, Town Clerk.

ELECTRICAL.—WANTED, an experienced TRAVELLER for Lancashire and Yorkshire, to go amongst Ironmongers and others using Electrical Appliances. State in confidence, what experience, and where, also age and salary wanted.—Address, "ELECTRICIAN," care of B. Wheeler, Advertising Agent, Pall Mall, Manchester.

WANTED, a DRAUGHTSMAN, one used to Telephone and Telegraph Instruments preferred.—Apply, stating salary required and experience, to 1013, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED, an ASSISTANT with technical training for Works Office, Drawing, Testing, Correspondence, &c No salary first 12 months.—Apply, MANCHESTER EDISON SWAN CO. (Limited), 14, St. Ann's-square, Manchester.

APPOINTMENT WANTED by experienced electrical and mechanical ENGINEER, A.M.I.C.E., and E.E., as MANAGER or SUPERINTENDENT of installation work. Well up in dynamo design, shipwork, estimating, and management of men. Highest references.—Address, 1138, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

DESIGNER (Ornamental Work) REQUIRES DAY WORK, or will for permanent situation, give in exchange, several excellent original designs.—Address, "P.," 15, Oaklands-grove, Shepherd's Bush, W.

ELECTRICAL ENGINEER (21) seeks ENGAGEMENT. Thoroughly experienced in Continuous Current Arc, Incandescent lighting, Accumulator and Power Plants. Good references.—"W. E. T.," 73, Excelsior-street, Waun Llwyd, Mon.

SITUATION WANTED in the Calibration of Electrical Measuring Instruments or Testing Current Meters. Has had entire charge of similar business for two years.—Apply to "A.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

TO ELECTRICAL ENGINEERS.—EMPLOYMENT WANTED by Wood Turner, used to Bench and French Polishing.—Apply, "A. B.," 57B, Grant-road, Clapham Junction.

TO COUNTY COUNCILS, CORPORATIONS and OTHERS.—ELECTRICAL ENGINEER desires ENGAGEMENT. Great experience in the laying and testing of Electric Light Mains, also Submarine Cables. For many years in the employ of one of the leading Telegraph Engineering and Electric Light Works. Highest references.—"ELECTRO," 44, Loftus-road, Shepherd's Bush.

AN established ENGINEER having offices in a central position, is desirous of meeting Inventors or Firms manufacturing Small Patented Specialities, Instruments, &c., used in Mechanical and Electrical Engineering, with a view to representing their interests in London. Address in first instance, No. 1127, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

ELECTRIC LIGHT INSTALLATIONS, AND THE MANAGEMENT OF ACCUMULATORS.

A Practical Handbook. Sixth Edition, revised and enlarged, with numerous Illustrations. **6s.**

"We advise every man who has to do with installation work to study this work."—*Electrical Engineer.*

PRACTICAL ELECTRIC LIGHT FITTING.

A Treatise on the Wiring and Fitting-up of Buildings deriving Current from Central Station Mains, and the Laying Down of Private Installations, including the Latest Edition of the Phœnix Fire Office Rules. By **F. C. ALLSOP,** Author of "The Telephones and their Construction." With 224 Illustrations. **5s.**

"We can strongly recommend the book."—*Manchester Examiner.*

New Work by **W. PERREN MAYCOCK, M.I.E.E.**

AN ELEMENTARY MANUAL OF ELECTRIC LIGHTING AND POWER DISTRIBUTION,

for Students preparing for the Ordinary Grade Examination of the City and Guilds of London Institute, and general readers. Part I. With 125 Illustrations. Crown 8vo. Paper covers. Price **2s. 6d.** Part II. *in the Press.*

By **STUART A. RUSSELL, Assoc.M.Inst.C.E., M.I.E.E.**

ELECTRIC LIGHT CABLES AND THE DISTRIBUTION OF ELECTRICITY.

With 107 Illustrations. **7s. 6d.**

"The various systems of main distribution, heating losses, jointing, cost of distribution, testing, safety devices, &c., are dealt with. . . . **A book of very great value.**"—*Electrical Review.*

"This book is one of the best that could be taken up by the student to give him a general knowledge of what is involved in the comprehensive title, 'The Distribution of Electricity.'"—*Nature.*

By **THOMAS H. BLAKESLEY, M.A., M.Inst.C.E.,** Hon. Sec. of the Physical Society.

ALTERNATING CURRENTS OF ELECTRICITY.

Third Edition, enlarged. **5s.**

"It is **written with great clearness and compactness of statement,** and well maintains the character of the series of books with which it is now associated."—*Electrician.*

By **JOSEPH POOLE, A.I.E.E.** (Wh. Sc. 1875), Chief Electrician to the late Lancashire and Cheshire Telephone Exchange Co., Manchester.

THE PRACTICAL TELEPHONE HAND-BOOK.

3s. 6d. With 227 Illustrations.

"It contains readable accounts of all the best known and most widely used instruments, together with a considerable amount of information not hitherto published in book form."—*Electrician.*

By **SYDNEY F. WALKER, M.I.E.E., A.M.Inst.C.E.**

ELECTRICITY IN OUR HOMES AND WORKSHOPS.

A Practical Treatise on Auxiliary Electrical Apparatus. With numerous Illustrations. Second Edition. **5s.**

"It would be difficult to find a more painstaking writer when he is describing the conditions of practical success in a field which he has himself thoroughly explored."—*Electrician*

"Mr. Walker's book is evidently the work of a practical man who has had much experience. . . . **The practical hints are likely to be of solid value.**"—*Saturday Review.*

LONDON: WHITTAKER and CO., Paternoster Square.

CALVERT'S MECHANIC'S ALMANAC FOR 1893.

(Price 4d.) Contains, besides other valuable matter, "Patents: Some Popular Delusions," by W. LLOYD WISE, Esq., J.P., C.C., Fellow of the Chartered Institute of Patent Agents.

MANCHESTER: JOHN HEYWOOD, Deansgate; and JOHN CALVERT, 99, Great Jackson-street.
LONDON: JOHN HEYWOOD, 2, Amen-corner.

JUST PUBLISHED, Crown 8vo, 620 pp., with 350 Illustrations, 12s. 6d., cloth.

THE STANDARD ELECTRICAL DICTIONARY.

A Popular Dictionary of Words and Terms Used in the Practice of Electrical Engineering, containing upwards of 3,000 Definitions. By T. O'CONOR SLOANE, A.M., E.M., Ph.D., Author of "Arithmetic of Electricity," &c.

LONDON: CROSBY LOCKWOOD and SON, 7, Stationers' Hall-court, E.C.

"THE PATENTEES' HANDBOOK,"

BY
J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,
CHARTERED PATENT AGENT,

Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books,

have weekly parcels from the Continent with all the new Scientific Books.

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS CO., LIMITED.

ELECTRICAL ENGINEERS, AND INDIA RUBBER AND GUTTA PERCHA MANUFACTURERS.

MANUFACTURERS OF

CABLES, WIRES, INSTRUMENTS, INSULATORS, DYNAMO MACHINES, MOTORS, ARC LAMPS & FITTINGS, BATTERIES, CARBONS, TORPEDO APPARATUS.

SPECIALITY.—Underground Electric Light System for High and Low Tension. The only System which has given complete satisfaction.

Contracts entered into for the Erection and Equipment of Central Lighting Stations, the Lighting of Ships, Factories, Houses, and the Supply of Complete Plant for Electrical Traction and Transmission of Power.

VULCANISED INDIA RUBBER.

HOSE, DRIVING BANDS, STEAM PACKING, WATERPROOF GARMENTS and FABRICS, SHOE SOLES, MATS, VALVES, BRAKE BLOCKS, WHEEL TYRES for CABS, CARRIAGES, BICYCLES, &c. SHEET, WASHERS, BUFFERS, SPRINGS, TUBING, SOLID CORD, FOOTBALL BLADDERS, LAWN TENNIS BALLS. MOULDED GOODS to any Pattern.

EBONITE.

Not affected by Vinegar or Hydrochloric or Acetic Acid.

SPECIALITIES IN EBONITE FOR CHEMICAL WORKS.

INSULATORS, BATTERY CELLS, SPEAKING TUBES, SHEET & ROD, SURGICAL APPLIANCES, PHOTOGRAPHIC ARTICLES, SCREW STOPPERS, PUMPS.

GUTTA PERCHA.

TUBING, BELTING, BUCKETS, BOSSES for FLAX SPINNING, GOLF BALLS, SHEET and TISSUE.

ESTIMATES & PRICE LISTS ON APPLICATION.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 765.—Vol. XXX. FRIDAY, JANUARY 13, 1893. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Though full particulars are not yet obtainable as to the Royal Commissioners' interim recommendations for establishing electrical communication between certain points on the coast and adjacent lightships and rock lighthouses, the fact that the Committee is making useful progress will be welcome news to most of our readers, and, we believe, to the public at large. We cannot doubt the success of the experiments, now that they are being seriously taken in hand. It may be hoped that one of the first points to be dealt with will be the Goodwin Sands, where, as may be seen in our Notes column this week, great expense was incurred on an unnecessary enterprise a few days ago, for want of intercommunication between the several lightships in that ill-fated region.

A common sequel to the remark that electricity is in its infancy is, that the day will come when electricity will be generated direct from coal. The waste involved by the intervention of the steam-engine, with the clumsy modes of raising steam and the clumsier ways of utilising it, are apparent to anyone who looks into the calorific values of fuel. One day a pyromagnetic generator claims to rank as a step in this direction, and, on the next, an improved thermopile is put forward with more pretentious promises. The principle of the one is so obscure and the action of the other is so complex, that the public, with that reverence for science as a thing they cannot understand—with a mental attitude, in fact, which to-day takes the place once satisfied by superstition—hope for much, expect less, and passing on to the next nine days' wonder, forget to be disappointed. Mean while, under their very noses, and, indeed, appealing through those gates of knowledge, gas-engines are running, and without dignifying them by the name of internally fired engines or endothermic generators, it is well known that they are beating the steam-engine, both in fuel consumption and in general economy. The important Paper by Mr. J. E. Dowson, of which we print an abstract in another column, makes a careful comparison between the performance of gas and of steam-engines for electric lighting. Our friends the gas journals are fond of accusing electrical engineers of prophesying that gas will be abolished. We have often heard of this prophet, but have never met him; the fear was evidently father to the thought. At the same time, Mr. Dowson offers a much more economical fuel than town gas, and it is to be hoped that some central stations in this country may be induced, at all events, to try a supplementary gas plant or two for day loads or for emergency use.

We alluded, in our issue of December 9th, to some experiments by Mr. Campbell Swinton, in which he succeeded in bringing an ordinary glow lamp to normal incandescence by means of a high-frequency current passed through the body. Mr. Swinton made the important suggestion that, owing to the crowding of the current to the surface of the filament, the resistance of the lamp became excessive; so that the lamp, instead of taking a current of a third of an ampere at one hundred volts, perhaps received the usual thirty watts by means of a very minute current at a potential of some thousands of volts. Prof. Elihu Thomson fully confirms this explanation in his letter, which will be found in our Correspondence Columns. That there was a considerable difference of potential between the lamp terminals was indeed proved by the fact that when it was lit in this way, sparks often passed between them.

Mr. Swinton has made another interesting experiment. When a wire was used to lead the current to the lamp, in place of the human body, the lamp was over-incandesced, so that the body clearly offers considerable impedance to the passage of high-frequency currents. This was further proved by again inserting the body in the circuit, and bringing the thumbs of the two hands together. Sparks about a quarter of an inch in length were found to pass between the two thumbs, and, when these occurred, the lamp glowed with increased brightness. These sparks, moreover, indicate a fact of considerable importance, since they show that the human body can withstand, without danger or inconvenience, a potential corresponding with a spark of a quarter of an inch in length, or about ten thousand volts. It has been often supposed that the human body acts like a condenser with regard to the passage of alternate currents. But this cannot be the case, for if so, the impedance offered to high frequency currents would be very small, and the application of ordinary voltages would be fatal.

In the *Philosophical Magazine* this month there is an article by Mr. Fernando Sanford, of Palo Alto, California, which is entitled "A Necessary Modification of Ohm's Law." The writer measured the resistance of a copper wire when surrounded by various gaseous and liquid dielectrics, and

Hosted by Google

found that its resistance altered considerably, sometimes by as much as 25 parts in 10,000. There is evidence that the measurements have been made with much care; but, for all that, the experiments given do not at all warrant the sweeping conclusion that the resistance of a metallic conductor varies with the dielectric surrounding it. An electrical resistance is one of those physical quantities which can be measured with extreme accuracy, and it is perhaps the quantity which has been most often measured. It is quite incredible that an alteration of the magnitude asserted can have escaped detection in face of so many years' use of the Wheatstone Bridge.

Not only is resistance the electrical quantity, any variation of which can most easily be detected, but Ohm's law is the law in which electricians rightly have more confidence than in any other. Before it is permissible to call a modification of it "necessary," it is clearly incumbent on the experimenter to show that in no other way can his observations be explained. But Mr. Sanford has not attempted this. According to him, "it seems clear that hereafter Ohm's law will have to be so modified as to take account of the dielectric surrounding a conductor, as well as the nature and temperature of the conductor itself." Apparently Mr. Sanford, by thus alluding to temperature, seems unaware that Ohm's law is only supposed to apply to a body whose physical state is kept unchanged, and that when the temperature alters, the resistance changes, not because Ohm's law ceases to be true, but because the body has a temperature coefficient.

It appears to us likely that the explanation of Mr. Sanford's results is to be found simply in the temperature of the wire. He finds that the resistance of the wire for the same temperature varies according to the dielectric in which it is placed. But the temperature he measures is not the temperature of the wire, but that of the dielectric in which the bulb of the thermometer is placed. The wire is thin, only one millimetre in diameter, but it seems a great assumption to suppose that the temperature of the wire is the same as that of the dielectric whatever the latter may be. The alteration in resistance, which is in most cases very much less than 25 parts in 10,000, or one quarter per cent., is immense if it is supposed to be due to an alteration in Ohm s law; but if it is merely due to change of temperature in a copper wire it corresponds at the utmost with little more than half of a degree centigrade. The wire is, of course, being heated by the current, and a slight change of temperature would necessarily result from change of emissivity owing to the different thermal properties of the various dielectrics used. The method described in the Paper, which might more appropriately have been entitled "Some Curious Discrepancies in Resistance Tests," may eventually be useful in investigations on emissivity.

In the December number of the *Journal de Physique* will be found an article on the Theory of Dimensions, written by M. Henri Abraham. To anyone interested in this subject, his Paper will prove well worthy of study. It is a clear and concise exposition of the difficulties met with in the theory of dimensions, and is enriched with a complete list of the various Papers, nearly sixty in number, which have been written on this subject since the original one appeared in Fourier's "Traité de la Chaleur." The main contention of M. Abraham is that, in determining the dimensions of any quantity, no relation ought to be considered which involves the physical properties of matter. To put this view in its simplest way, it may, for example, be said that to connect the dimensions of the unit of mass with those of the unit of length, simply because the mass of a cubic centimetre of water is one gramme, is quite unjustifiable. To conclude from this fact that the dimensions of a gramme mass are the same as the cube of a length, would be wrong, owing to the fact that the physical properties of a unit volume of water have been ignored. The proposition advanced by M. Abraham is not a new one, but, carried out logically, it leads to the result that it is impossible, either in the electrostatic or electro-magnetic systems of units, to completely express the dimensions of the various electrical quantities in terms of only the units of length, mass, and time.

Havre.—An electric tramway concession has just been granted to a M. Pierre Burton.

Electric Railway Enterprise in France.—According to *L'Electricien* a scheme is on foot for running an electric railway from Besançon to the Swiss frontier, 40 miles off.

Brighton.—At the last meeting of the Town Council the new tariff for electricity consumers was announced. (See Mr. Arthur Wright's letter to *The Electrician*, December 23, p. 221.)

Halifax.—At its last meeting the Town Council decided to take steps for supplying electricity under its Provisional Order of last year, and that an electrical engineer should be appointed at a salary of £200 per annum.

Cardiff.—The Electric Lighting Committee reported at the last meeting of the Town Council that the Town Clerk had been authorised to apply to the Local Government Board to sanction the borrowing by the Corporation of the sum of £32,500, for the purpose of erecting an electric lighting station. The minutes were adopted.

The Eastern Telegraph Company notify that submarine telegraph communication is restored to the Cape of Good Hope and South Africa.

Presentation to Mr. H. J. Vose.—Mr. H. J. Vose, who has recently been appointed to the post of Superintending Engineer, Post Office Telegraphs, for the South Wales District, was on Thursday, the 5th instant, presented with a very handsome dining-room clock by his late colleagues of the Engineer-in-Chief's Office, General Post Office. The presentation was made by Mr. J. Hookey, Assistant Engineer-in-Chief, and Mr. Vose, in a few well-chosen words, thanked him and the donors generally for the gift.

Howard Lectures.—The first of a course of Howard Lectures, by Prof. W. Cawthorne Unwin, on "The Generation of Power at Central Stations, and its Distribution," will be delivered this evening at the Society of Arts. The course will consist of

Hosted by Google

six lectures, to be delivered on Friday evenings up till February 17th. The lecturer will deal with the commercially available sources of mechanical energy, and the method of distributing it, treating in the last three lectures the hydraulic distribution of power, the transmission of power by compressed air, and the distribution of mechanical energy by electricity.

Crompton-Howell Batteries for an American Central Station.—"It has been a source of astonishment to foreign engineers," says the *Electrical World* of New York in its issue of December 24th, "that the use of secondary batteries in central station work has been entirely neglected in the United States. We are glad to announce that during the coming week one of the Edison stations in this city will connect a secondary battery plant to its mains. The batteries are of the Crompton-Howell type. The experience with this pioneer plant will be watched with great interest, and may lead to considerable re-modelling in our continuous-current central station practice."

The Indian Government and the Australasian Cable Rates.—The Indian Government has yielded to the remonstrances addressed by the official representatives of the Australian colonies to the Secretary of State for India recently, and have consented to abandon their intention of increasing the transit charge on cable messages from England to Australia which pass over the India land lines from 35 to 50 centimes per word. The Indian Government considered that, as the charge for cable messages to Australia and *vice versâ* has been increased from 4s. to 4s. 9d. per word, they were justified in increasing the land rate by 15 centimes. Now, however, they will adhere to the old rate of 35 centimes so long as the cable tariff remains at 4s. 9d.

Manchester.—The Municipal Electric Light Station, which is now nearly ready, promises to be second to none in the country. Its dimensions are 210ft. by 80ft., and 40ft. high. The engine-house is a fine building, lined with glazed brick throughout. The gantries have been erected for the electric travelling cranes along each of the two bays; the massive concrete foundations are in, and the bed bolts and belt racewells formed, preparatory to setting the engines and dynamos, which are all ready for delivery. The beds are built and the boilers are ready for fixing immediately upon completion of the large overhead tank, which is well advanced. The chimney, 240ft. in height, is finished. The economiser house is in progress, and such a proportion of the street mains and feeders have been laid as shortly to warrant the issue of forms of application for service connections. The demand is likely to be great from the commencement.

Automatic Electric Railway Signals.—In his report on the Thirsk disaster, Major Marindin remarks that it is well known that there are in existence several combinations of electrical and mechanical appliances, the use of one of which, so long as everything was maintained in good order, would make it impossible for such an accident to occur, unless a driver were to run deliberately past fixed signals. Although the mistakes made by signalmen are remarkably few, considering the enormous number of train-signalling operations performed daily, Major Marindin thinks it is the duty of all railway companies to adopt, upon their important lines at any rate, some safety appliance which will prevent a mistake made by one signalman from causing an accident. Devices of the kind have been in general use for some years upon three lines of railway, and in partial use upon others, both in the United Kingdom and abroad, and have been found satisfactory.

The Electric Transmission of Power from Coal Fields.—"We believe the electrical transmission of power from the coal fields to the metropolis," says *Industries*, in concluding its running commentary on Mr. Thwaite's recent Paper, "will be in practical working order before very many years. The chief difficulty in the scheme is to get the capital. There is no reason why Mr. Thwaite should not begin by transmitting the power to manufacturing towns where the load factor will be better than in the metropolis. The power can be used for lighting purposes and driving motors first, and it may come in for other purposes later. A striking feature about this scheme is that the fuel forms an exceedingly small fraction of the cost of the power. This shows that power gained from a waterfall is not necessarily sensibly cheaper than that taken from coal where it is cheap. Comparing this scheme with that connected with Niagara, while the Niagara scheme has a certain advantage in the way of water, the English scheme has a much more solid advantage in having its customers alreading existing close to the central station."

The Liverpool Overhead Railway.—A trial run over this line was made on Saturday last. The train consisted of two carriages, and the passengers included Sir A. B. Forwood (chairman of the Company) Mr. Todd (of the Electrical Construction Corporation), and others. The proceedings were under the direction of Mr. S. B. Cottrell, general manager and resident engineer of the Company. The train ran to Bramley Moore Dock, where the generating station is situated. There are four horizontal compound 400 I.H.P. engines, built by Messrs. John Musgrave and Sons, each driving an Elwell-Parker dynamo; these are supplied with steam by six Lancashire boilers, also built by Messrs. John Musgrave and Son, and fitted with Vicar's mechanical stokers, in addition to which there is an arrangement of mechanical coal bunkers, by which all handling of coal is entirely obviated, the coal being dropped into them from the high level coal railway. The current is carried north and south along the railway by a steel conductor placed on porcelain insulators, supported upon cross timbers between the rails on each line. A feature on the railway is Timmis's system of automatic signals, electrically worked by the trains themselves.

Electric Transmission of Power in Sweden.—An important power transmission installation, says our Scandinavian Correspondent, has been decided upon at the large Gröngesberg mining concern in Sweden. It will be used for the raising of ore and water, and will be carried out during the present year by the Swedish Electric Company. The five steam-engines, which have hitherto been used at different places, will be exchanged for five electric motors of the same power; and, in addition, there will be an electric light installation, comprising in the first instance 30 arc and 150 incandescent lamps. The power station will be at the Hällsjön, where four 100 H.P. turbines will be laid down. As the waterfall is of considerable height, the electric generators will be placed on the same axle, so that no belting or transmission will be necessary. The high-pressure current from the transformers is carried along 4mm. and 3mm. conductors to the mines, where the pressure is reduced. The distance from Hällsjön to Björnberget is six miles; here a certain amount of energy is used for light and power. From Björnberget it is about two miles to the first Gröngesberg central station, where another portion of the power is used; and from there it is some 600 yards to the second Gröngesberg station; and, finally, there is a stretch of one mile to Lomberget, where the balance of the power is absorbed. The installation will be the largest in Scandinavia, and the first of its kind in the district.

Hanley.—A special meeting of the Town Council was held last week, upon special requisition, to consider the position of the Council with regard to the Electric Lighting Provisional Order, and to pass such resolutions thereon as might be deemed advisable. The Corporation, as we have already stated, have obtained an Order, and have entered into a contract with the Brush Company, and a few weeks ago a Local Government Board Inquiry was held with respect to the application by the Town Council for sanction to borrow £21,000 required to carry out the scheme. The conveners of this meeting stated that they had been led into voting for the scheme by the belief that there was no alternative. They now pointed out that under clause 59 of the Order the Corporation was authorised to transfer the powers. The Mayor said that the resolution was out of order until the Council had rescinded a resolution passed on December 10, 1889, not to entrust any further powers for artificial lighting within the borough in the hands of any company, and a resolution of September 16, 1892, accepting the tender of the Brush Company. Those resolutions could not be rescinded without notice. But besides all this, the town clerk had obtained the opinion of the standing counsel of the Municipal Corporations Association, who stated that the Corporation had entered into a contract with the Brush Company, and would be still bound by that contract

Hosted by Google

whether the resolution was rescinded or not. Notice was then given of intention to move the rescinding of the resolutions mentioned by the Mayor. Finally, however, it was moved and carried by 15 votes to 8 that the Council decline to reopen the question of the Electric Lighting Provisional Order.

Fashion in Engineering.—On December 16th last, in an article on "A Ballistic Galvanometer," allusion was made to those "causeless *nuances*" which distinguish the electrical machinery and apparatus of America from that made nearer home. In its issue of December 30, 1892, our able contemporary, the *Engineer*, holds forth on this very text, but referring more particularly to steam-engines; and the reasons it gives for these apparently fortuitous differences are worth noting. "It is surely an interesting question," says our contemporary, "Why does this difference exist? It seems certain that the design, or the peculiarities of design of the American engine, confer no special advantages on it, either from a maker's or a user's point of view. We think that the answer must be sought in the men who make and use steam-engines. There is a wide difference between an Englishman and an American. There is a difference in speech, in modes of life, in methods of thought; and what the man is, that will his engine be. It is, in short, a race difference, an ethnological difference, and that in its turn is a result of climate and surroundings. This may seem at first sight a curious and almost esoteric kind of speculation, but the moment the idea has been mastered we find ourselves in possession of a key to much that is, without it, perplexing to a degree. The engine itself, the machine, is neither better nor worse for being made on English or on American lines, and it assumes certain characteristics in the States, and certain different characteristics in this country, simply because the designers cannot help it; and a noteworthy thing is that English engineers who settle in the United States very soon give up their notions and adopt American ideas, while American draughtsmen in this country take up English ideas; and when this does not occur with the first generation, as is sometimes, although rarely, the case, it invariably does in the second generation."

The Pacific Cable Scheme.—The Canadian Government having decided to ask the Imperial authorities to appoint a Commission to inquire into the feasibility of the scheme for a Pacific cable, a representative of Reuter's Agency called upon the various Agents-General of the Australasian Colonies to ascertain their views on the subject, and what support was likely to be forthcoming from their respective Governments in this connection. Sir Andrew Clarke, the Acting Agent-General for Victoria, said he should strongly urge his Government not to entertain any idea of granting a subsidy for the purpose. From a strategical point of view the cable would have no importance whatever, and would be no practical help in time of war. The existing cables to Australia adequately carried all the traffic. He would favour the scheme, however, on the principle of letting "dog eat dog." Sir Saul Samuel, Agent-General for New South Wales, preferred to express no opinion. Mr. Westby Perceval, Agent-General for New Zealand, stated that, although in receipt of no instructions from his Government, he would favour the proposal of an alternative cable to Great Britain which would run entirely through British territory. He would, however, add that the present communication was sufficient for the traffic. Sir James Garrick, Agent-General for Queensland, believed his Government would look very favourably upon the scheme. Sir John Bray, Agent-General for South Australia, on the other hand, expressed the opinion that most of the Australian Governments would not be prepared to go to any expense for an alternative cable, the existing one meeting all requirements. Sir Edward Braddon, Agent-General for Tasmania, stated that he could not say what position his Government would take up in the matter.

Edinburgh.—The peripatetic tendencies of Electric Lighting Committees not unnaturally afford considerable amusement to the gas interest, and in a recent issue the Scotch correspondent of the *Journal of Gas Lighting* mingles didactics with merriment in adverting to the doings of the Edinburgh Committee. The following is a brief abstract of these remarks. The argument that because electrical engineers are inclined to be reticent, *ergo* they are immoral and the electrical industry is in a bad way, while comforting to gas engineers, is somewhat elliptical:—

> Mystery deepens as one comes to know more of that famous deputation from the Edinburgh Town Council to the Electric Lighting Works of the South. The deputation are in the throes of preparing their report. What is the difficulty? They have received information which they are not permitted to make use of. In some of the works which they visited they were admitted upon sufferance—the condition being imposed that they would not publish certain things which were communicated to them. I have hitherto regarded the electric lighting enterprise as one in which there was a great amount of solidarity; but this incident throws a side-light upon the doings of the fraternity who are engaged in it, and shows them to be each fighting fiercely "for his own hand." A brotherhood which is so veiled does not convey to an outsider the impression that they are engaged in an industry of a very healthful nature. I understand that the deputation are not to recommend any particular system, but are to lay before the Council the information they have received, and ask power to call in a superior expert to advise them which to adopt. The deputation seem to have gone into their work with vigour, for they not only looked at works, but interviewed customers as to their experiences. What is of interest at present is that, before starting, they seem to have been aware that they would not voluntarily receive all the assistance which they desired, and to have taken means to ensure that they would not be thwarted. The incident illustrates, on the one hand, the futility of sending deputations from public bodies to inquire into private businesess; and, on the other, the unsettled and unsatisfactory position of the electric lighting industry, when, while making a show of being frank and open, subterfuge has to be resorted to by its exponents. It also shows that electric lighting has not, in the course of its history of about twenty years, become one of the public agencies in civilisation, but is still matter of individual speculation both on its scientific and on its financial side. It is so far from having been tried and found efficient, that its promoters shrink from allowing it to be tested openly; and those who adopt it, have really to take a leap in the dark.

The Need of Coast Communication.—An instance of the amount of expense and time which would be saved by telegraphic communication with lightships occurred at Ramsgate only on Monday last. Shortly before one o'clock signal guns were heard at sea, and almost immediately the "Gull" lightship began making the usual signals for assistance from the shore. These were replied to from Ramsgate Pier, and the harbour tug "Aid," with the lifeboat "Bradford," proceeded to sea. The lugger "Champion" also put off, and the Broadstairs, Deal, and Walmer lifeboats all responded to the call, together with two other tugs. The weather was very thick, but there was no sea on. The Ramsgate tug "Aid," on arriving at the "Gull" lightship, learned that the lightsmen there had heard guns, which they believed to be signals proceeding from the East Goodwin lightship, and they had at once passed them on to Ramsgate. The tug and lifeboat then made for the other side of the Goodwin Sands, keeping a good look-out meanwhile for a wreck. On reaching the East Goodwin lightship the lightsmen there stated that no signals had been made by them. After cruising about, the tug and lifeboat returned to Ramsgate between four and five o'clock, having discovered no traces of a vessel in distress. The lugger "Champion" was equally unsuccessful. As the cost of the Ramsgate tug and lifeboat going to sea is alone about £20, and other lifeboats and tugs are also often engaged on a fruitless errand, owing to false alarms or mistaken signals, the matter is an important one.—A public meeting was held on Tuesday evening last at Ramsgate, to urge the Government speedily to carry out the proposed electric communication between lightships and the shore to prevent such loss of life as resulted in the recent wreck of the "Dilsberg" on the Longsand. The Mayor of Ramsgate presided, supported by Mr. E. J. Hobbs, the promoter of a scheme of electric communication with lightships. Mr. Hobbs proposed a resolution to the effect that the Government be petitioned to investigate the facts connected with the wreck of the "Dilsberg" on the Longsand on December 9th last with a view to ascertaining whether the disaster might not have been averted had electric or telephonic communication as experimentally provided in 1885 and 1886 now existed. The resolution was carried unanimously. After other speeches had been made, the Rev. T. Hancocks moved that the Government be requested to establish an effective system of telegraphic or telephonic communication between lightships, lighthouses, and the shore, that the loss of life and property at present existing might be prevented. This resolution was also adopted.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 186.)

24. The Maintenance of Home and Continental Cables.—There are altogether 101 telegraph cables, in all 882 miles, in and about the British Isles, by which the most important outlying islands are connected with the mainland, and various rivers, estuaries, bays, and arms of the sea crossed. Besides these the English Government own two cables to Holland (219 miles) and one to Germany (232 miles), and have a joint ownership in five cables to France (195 miles), one from Jersey to France (16 miles), two to Belgium (108 miles), and one to Germany (211 miles). There are also two cables owned by the German Government, one to Lowestoft (226 miles), and one to Ireland (847 miles). These cables, amounting to 2,936 nautical miles, are kept in repair by H.M. telegraph ships, the "Monarch" and the "Lady Carmichael," expenses of maintenance being borne by owners and shared by joint owners. It is of the latter vessel that this paragraph is mainly descriptive, the illustration (Fig. 86) being from a photograph taken by Mr. W. R. Culley, chief electrician on board, and of the Government Depôt at Dover, to whom the writer is indebted for valuable information on the work of these ships. This vessel originally belonged to the Submarine Telegraph Company, who owned the two Belgian and four French cables. Since the English Government purchased this vessel, about four years ago, and with the respective Governments effected a joint purchase of the above cables, she has continued to keep them in repair, but when not so engaged is often employed on other lines. The mileage given above is considerably more if measured in miles of copper conductor, many of the cables enumerated being multiple, with from two to seven cores. The cores of all such cables are laid or stranded together with a lay of about 12ft., served with yarn and then sheathed; but on repair work, when a splice is made the cores are jointed so that the conductors lie parallel, not made up in a strand as they existed before, which takes much more time to do. It is, however, necessary to strand them when a splice is made in the London-Paris telephone cable (between Dover and Sangatte), the joints in the cores of this cable being made so that the four conductors are stranded in the proper lay of 12ft., as the good working of the telephones at each end depends upon the neutralisation of induction by twisting the wires. The landline wires, for the same purpose, are fixed so that they make a complete turn round each other every fourth pole.

* All rights reserved.

The "Lady Carmichael" is a trim little paddle steamer, with a displacement of about 760 tons, at a mean draught of 10ft., and measuring 167ft. by 27ft. by 12ft. deep. The action of the paddles on the water in giving an *immediate* effect one way or the other is greatly appreciated. When a sudden stoppage is required the blades of a propeller have not the same resisting surface to check the momentum of the ship, and cannot make such way per revolution astern as ahead, whereas paddles are equally as good. With disconnecting paddles, as fitted to this ship, either of which can be thrown out of gear in an instant, very quick turns and movements can be made, and the experience gained is that for shallow water and in strong tides there is nothing to beat it. Drawing as she does less than two fathoms of water, this vessel is very useful for repairs close in shore.

On the outside of the ship, just below the bow baulks, are fixed narrow footboards or platforms, one on each side, which the men engaged in putting stoppers on the cable stand upon while so engaged, being held up under the arms by a bowline. All work is done from the bows, one sheave only being fitted. The cable gear was constructed at the Thames Iron Works Company to the designs of Mr. W. B. Esson, and is driven direct by a pair of inclined cylinders, the same as that on the Great Northern Company's ships. The first-motion shaft (at the top in Fig. 87), carries the crank disc, four excentric sheaves (two for each valve, with links for reversing), and a pinion of 14in. diameter, gearing into one of 22in. on the intermediate shaft, the relative speeds of the shafts being inversely as their diameters. A pinion of 12in. diameter on the intermediate shaft drives the drum spur wheel of 6ft. 4in. diameter, reducing the speed further in the proportion of $6\frac{1}{3}$:1, or a total reduction of speed in the proportion of 10:1. With this reduction the gear lifts ten tons at the bows, but as there is no other purchase arranged with a reduction of, say, 20:1 or 30:1, the maximum strain is limited to the above weight. With heavy multiple cables, especially when buried, the strain in picking up often reaches 30 tons, and to meet this strain a steam winch is called into requisition, the barrel of which is driven with a slow motion by a worm, allowing the engines to keep their speed and perform their full work per minute.

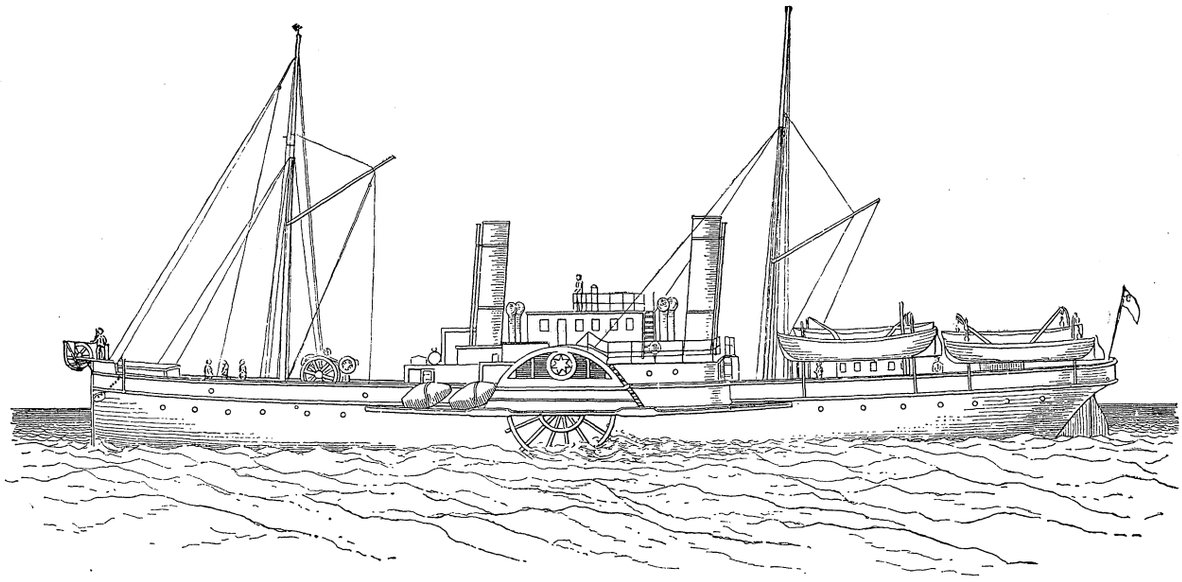

FIG. 86.—H.M. Telegraph Ship "Lady Carmichael."

For paying-out, the pinion driving drum is thrown out of gear, and the drum used with the brake. When up to buoy the drum is required for picking up buoyed end, so the turns of cable are taken off it, first removing the forward knife. Before taking the turns off, a little slack is payed out, and then the end stoppered at bows. When removed from drum the cable is laid over two forks on standards in line from bows to tank. This keeps it in a convenient position, and clear of the

Hosted by Google

gear, and the drum and gear are then at liberty for picking up buoyed end. Steam steering gear is fitted, the wheel-house being on bridge deck level. A neat part of this gear is the arrangement for setting the limit to which it pulls over the

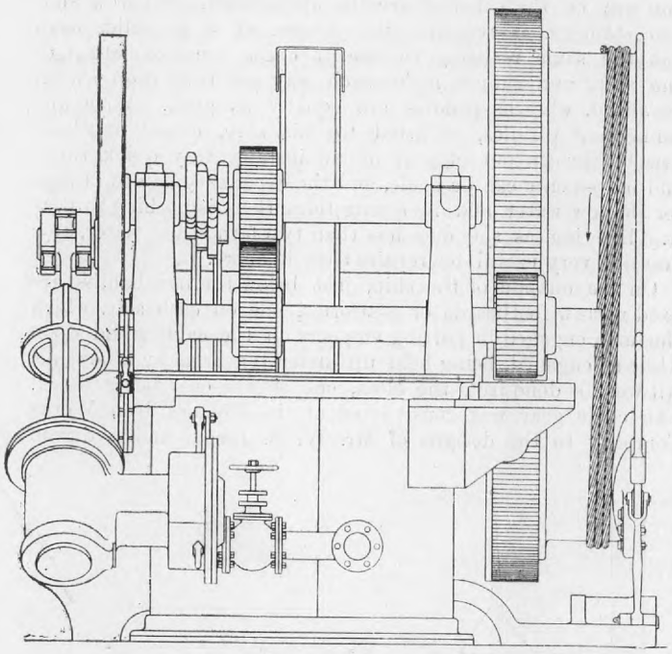

FIG. 87.—End View of Cable Gear.

rudder either way. The engine is by this device stopped when it has shifted the rudder by a predetermined amount, and the wear and jar produced in spinning the wheel a little too far, and going hard over, is prevented.

The chart room is on the same deck, and contains a large store of charts with the routes of the various cables round the British Isles, and positions where repairs or changes of route and splices have been made. One of the most remarkable of these is that showing the course of the London-Paris telephone cable laid by the "Monarch" early last year. Met by heavy weather soon after leaving the French coast, she was unable to continue paying out cable in the proper course; and not wishing to cut it, ran before the storm, paying all out and buoying the end. When the weather subsided, she picked it up and relaid it, but not in a straight course.

This cable, which was manufactured by Messrs. Siemens Brothers, under the supervision of the Post Office Engineers, contains four separate conductors, two for each circuit. After stranding the cores the whole is served with tanned hemp, and the outer sheath is of 16 galvanised iron wires, each 0·28in. thick, with a breaking stress of 3,500lbs. The sheathing wires are protected by a coating of gas-tar and silica. The insulation of the copper conductors is made up entirely of solid gutta-percha to 300lb. per knot, no Chatterton's compound being used. The shore ends of this cable do not differ from the main portion—that is, the sheathing is the same throughout, and, indeed, unless the ground is very bad, it is quite unnecessary to increase the size of the sheathing wires for the shore ends of multiple cables. The weight of each conductor is 160lb., and resistance about $7\frac{1}{2}$ ohms per knot; while the cores have a capacity of 0·3045 microfarads, and 2,000 megohms per knot at 75° F.

The testing room on the "Lady Carmichael" is remarkable for the very few instruments used. Instead of a couple of reflecting galvanometers and a mirror there is only one Morse instrument, and a simple compass card galvanometer. The latter stands on a small table mounted on gimbals, and is found quite sensitive enough for all the tests required, as everything is done by the bridge, in which method the needle is balanced to zero. The loop test is frequently in use, so many of the cables being multiple with spare insulated conductors to use as returns for the metallic circuit. In localising faults in single cables, and breaks in multiple and single core cables, when no insulated return conductor is available, it is found that the well-known "polar" tests of Mr. Lumsden (chief electrician to the "Monarch") are more to be relied upon than any other methods. These tests are fully described in "Kempe's Testing" and "Culley's Telegraphy." The Mance test is seldom used except as a check, and faults of high resistance are rare except in multiple cables, in which case they are readily localised by the loop. Insulation of cables after repair is proved on the bridge. On the wall is fixed a terminal board with six insulated terminals leading to cable in tank and six to bows, so as to be prepared for multiple cables. Battery commutators are also fixed for changing battery power, the cells used being Leclanché. As far as testing is concerned this completes the entire kit; while for speaking to shore, the distance being comparatively short, the Morse instrument is all that is required. A smart repair was effected on one of the Channel cables by this vessel on November 25, 1891. Leaving Dover Harbour at 4.45 a.m. for South Foreland, she proceeded to the position of break, 12 miles out, grappled for the two ends, and had the circuits through at 6.45 p.m., arriving back at Dover at 9.30 p.m. same day. The distance steamed was 32 miles in all, and the time from leaving to her return to harbour $16\frac{3}{4}$ hours, and this with four extra large joints to make.

While referring above to the cables to Belgium and France kept in repair by this vessel, it may be of interest to note

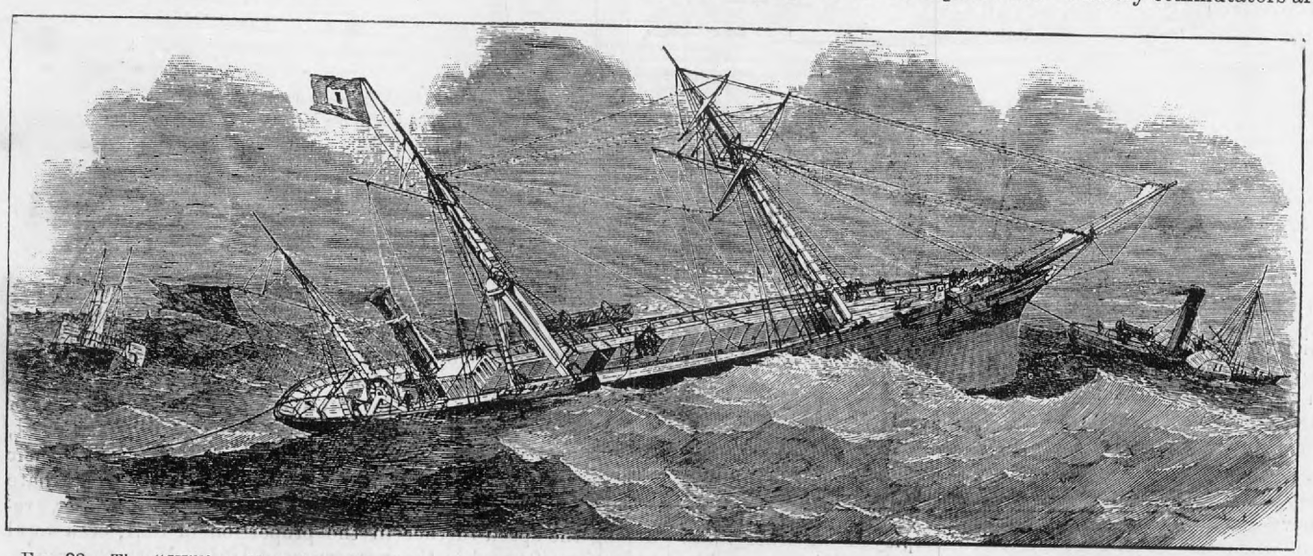

FIG. 88.—The "William Hutt" Laying Cable to Belgium in 1853. (This Illustration is reproduced from the *Illustrated London News* of May 14th, 1853, by kind permission of the Editor.)

Hosted by Google

that two very old cables are amongst their number, and still in first-class working order. One is that referred to in the last paragraph (23), viz., the multiple cable of four cores laid in 1851 between Dover and Calais, the first sheathed cable ever laid. Since that date so many repairs have been effected that only a very short length of the original cable remains, but the line, as a means of communication, has remained intact. The other is the Belgium cable from South Foreland to Middlekerke, near Ostend, laid in 1853, which was laid by the screw steamer "William Hutt," the illustration (Fig. 88) of this early cable ship so engaged being reproduced from that in the *Illustrated London News* of May 14th of that year. It is a six-core cable, and cost £471 per mile, more than double what a similar one would now. It took over three months to manufacture this length of 70 miles, and the rate of coiling into the steamer's hold from the factory was only one mile per hour. Cable can now be coiled into tanks on board, a distance of 200 yards from the factory, at a speed of over 5½ miles per hour, as instanced by the "Silvertown," in which vessel, on one occasion in 1882, were coiled 2,370 knots for the Central and South American line, in 22 days, the greatest length coiled in twelve hours being 65 knots; while on another occasion, in 1887, she took aboard 64½ knots in eleven hours twenty minutes.

The "William Hutt," commanded by Mr. Palmer, of Gateshead, who built her, was towed during her expedition and accompanied by two vessels of the English and one of the Belgian Navy, the former marking out the course by buoys. Shore ends were landed by fishing boats. On the English coast, the "William Hutt" being anchored 500 yards from shore, 200 yards of shore end was first coiled into a large boat, and as this boat rowed to shore six other boats in turn supported cable as it was handed out from ship. (Buoys or barrels are used instead of boats now.) On the first boat reaching shore, the 200 yards were uncoiled from it and hauled up the beach by forty men, the end being connected to a speaking instrument for communicating with ship. The whole fleet of fishing boats was towed across to the Belgian coast to assist in landing the shore end there. This cable was manufactured by Messrs. R. S. Newall and Co. to the specification of Messrs. Wollaston and Crampton, engineers, and was laid under the direction of the above-named firm.

(To be continued.)

THE IMPEDANCE OF BRANCHED CIRCUITS.

BY ALEX. RUSSELL.

The ordinary algebraical formula for giving the solution of this problem is complicated and unsuitable for arithmetical calculation. The impedance can, however, be calculated graphically without much difficulty, and the method is instructive, as the final figure shows at a glance the relative phases of the various currents. A geometrical solution for the case of

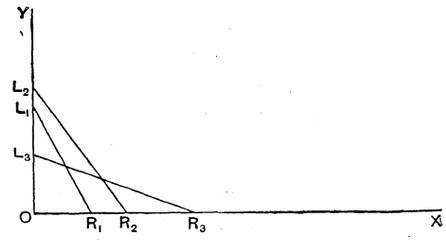

FIG. 1.—Impedances and Angles of Lag.

two inductive circuits in parallel is given by Dr. Fleming in the "Alternate Current Transformer," Vol. I. The drawback to this method is that the equivalent resistances and impedances are all given in different scales.

The current in the branch (R_1, L_1) must then

$$= \frac{E}{\{R_1^2 + p^2 L_1^2\}^{\frac{1}{2}}} \cos(p t - \alpha), \quad \ldots \quad (1),$$

where $$\tan \alpha = \frac{p L_1}{R_1}.$$

If C_1 be the maximum value of the current in this branch, then $$C_1\{R_1^2 + p^2 L_1^2\}^{\frac{1}{2}} = E. \quad \ldots \quad (2).$$

Now, the instantaneous value of the current before division is equal to the sum of the currents after division. We know, therefore, that the main current follows the harmonic law, and that its value is found by a theorem which is exactly analogous to the method in statics of compounding forces into a single resultant by the polygon of forces.

In order to get lines proportional in length to the currents we have first to construct lines equal to the impedances, $\{R_1^2 + p^2 L_1^2\}^{\frac{1}{2}}$. . . . Draw two lines (Fig. 1), O X, O Y, at right angles to one another, and measure lengths $O R_1 = R_1$ . . ., $O L_1 = p L_1$ . . ., and join L_1, R_1. . . . Then the lengths of the lines $L_1 R_1$, . . . give the impedances of the various coils, and the angles α, β . . . give the lag of the currents in the coils behind the applied E.M.F.

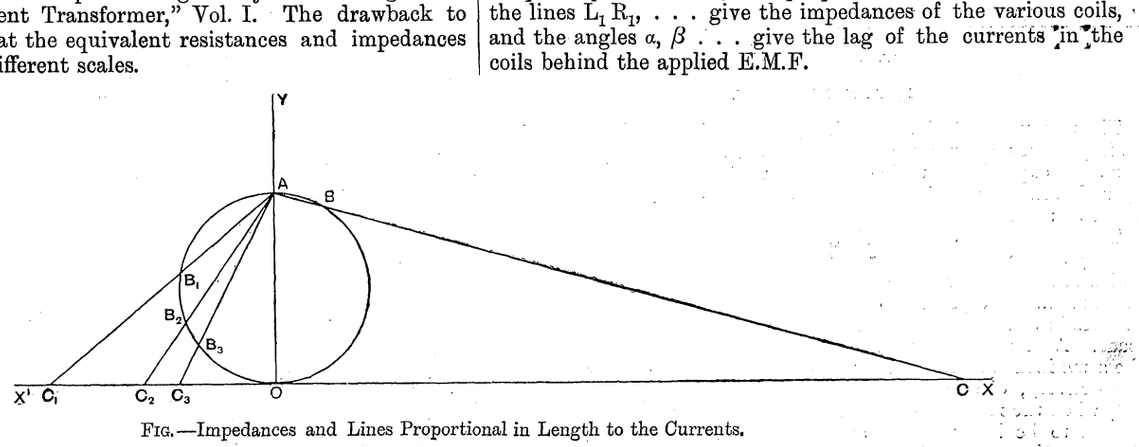

FIG.—Impedances and Lines Proportional in Length to the Currents.

We suppose that there is no appreciable mutual induction between the coils, that their coefficients of self-induction are constant, and that the applied E.M.F. follows the harmonic law.

Let the coils, which are all placed in parallel, have resistances R_1, R_2, . . . and coefficients of self-induction L_1, L_2, . . . and let the applied E.M.F. be E cos $p t$, where p is equal to 2π multiplied by the frequency of the $\sim$.

In Fig. 2 take any point A in O Y, and on O A as diameter describe a circle, O A being greater than the largest impedance. Draw chords $A B_1$, $A B_2$ . . . equal in length to $L_1 R_1$, $L_2 R_2$ . . ., and produce these lines to meet X X¹ in C_1, C_2. . . . Now, from (2)

$$C_1 . A B_1 = C_2 . A B_2 = \ldots = E$$

and $$A C_1 . A B_1 = A C_2 . A B_2 = \ldots = O A^2$$

Hosted by Google

It follows that A C_1, A C_2 . . . are proportional to the currents in the coils.

Now (Fig. 3), make the angles C_1 O E, C_2 O E. . . . equal to α, β . . . , and measure lengths O C_1, O C_2 . . . equal to A C_1, A C_2 . . . (in Fig. 2). From C_1 draw C_1 D parallel and equal to O C_2, and from D draw D C parallel and equal to O C_3, and so on if there are more than three branches; join O C. Then O C is proportional to the current before sub-division. The

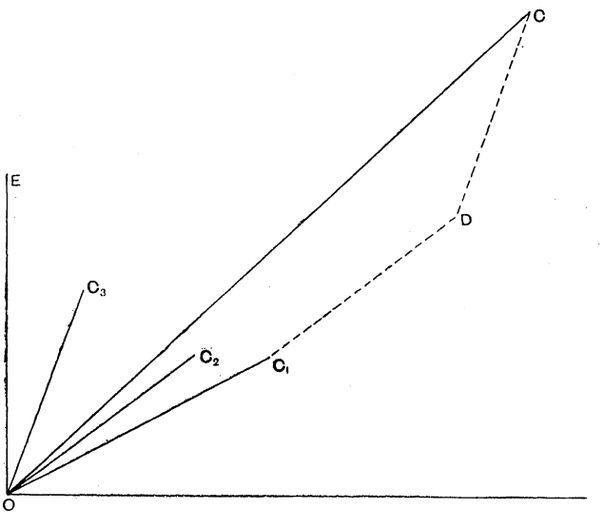

FIG. 3.—Phases and Magnitudes of the various Currents.

lag of the current O C behind the E.M.F. is obviously the angle C O E, and the difference of phase between the various currents can be measured from the figure. To get the joint impedance, make A C (Fig. 2) equal to O C (Fig. 3), and let it cut the circle in B. Then the length of A B is the resultant impedance. From the formula given by Lord Rayleigh (*Phil. Mag.*, 1886), we see that

$$\frac{1}{A\,B^2}=\left(\frac{R_1}{R_1^2+p^2L_1^2}+\ \ldots\ \right)^2+p^2\left(\frac{L_1}{R_1^2+p^2L_1^2}+\ \ldots\ \right)^2,$$

which suggests other geometrical methods for calculating A B.

The above method is also applicable to cases where there are condensers in the circuit, by considering a condenser as a resistance coil $\left\{0, -\frac{1}{C\,p^2}\right\}$.

A DIFFERENTIAL WATTMETER FOR ALTERNATING CURRENTS.*

BY A. E. KENNELLY.

The measurement of the efficiency of transformers is necessarily an important matter, for, setting aside the cost of the power that has to be expended in their excitation, wasteful transformers must, by undue heating, limit to a greater or less degree the output they could be made to yield with better materials or proportions.

The earlier and calorimetric tests of transformers† have been latterly almost entirely superseded by electrical wattmeter methods, which have themselves been tried in a variety of forms‡. These instruments are capable of determining with all desirable precision the loss in transformers that are idle or that are worked on light loads. Although two such instruments, or two measurements with the same instrument, one for the energy absorbed, the other for the delivery, enable the efficiency to be determined at any load, yet, when the readings of the instruments are large, they are well known to be less reliable, and the most recent advances have, therefore, been made in the direction of null methods, which Dr. Sumpner§ and also Dr. Hopkinson§ have used with excellent results.

The object of this article is to describe a differential wattmeter that has been constructed and tested for the last nine months at the Edison Laboratory. This instrument is a double electro-dynamometer of the Kohlrausch unifilar type. These two dynamometers are arranged as wattmeters with their suspended coils rigidly connected by an aluminium shaft 8cms. long. The upper wattmeter is in the primary circuit of the transformer to be tested, the lower in the secondary. The intake is, therefore, measured by the former, and the output by the latter, so that when the sensibilities of the two dynamometers are adjusted to equality, that is to say, when they are balanced differentially, the reading of the torsion head corresponds to the loss of power in the transformer due to all causes combined—hysteresis, C^2R, eddies, and radiation.

Thus, assuming that the sensibility of each dynamometer was such that one degree of torsion represented an activity of five watts, and that they were independently inserted in the primary and secondary circuits of a 20 kilowatt transformer worked at full load, the upper instrument would indicate, say, 20,750 watts with a torsion of 4,150deg., the lower 20,000 watts with a torsion of 4,000deg. Such a degree of sensibility would be, of course, quite impracticable, but mounted in combination with a common suspended system, the resultant torsion would only amount to 150deg. An uncertainty of 1 per cent. in the indications of the independent instruments would affect the results to a range of 207·5+200, or 407·5, watts. In the differential instrument, 1 per cent. deviation at the same load would represent 1·5 watt error.

The framework of the instrument is entirely of hard rubber, supported by a stout brass tripod. To avoid frequent repetitions, we may denote the upper dynamometer's fixed coil by U, its suspended coil by *u*, and the corresponding coils of the lower dynamometer by L and *l* respectively.

In a differential instrument of this description it is, of course, essential that U should have no effect on *l*, and likewise L none on *u*, so that the mutual inductance of these pairs of opposite coils must be negligibly small. This result is mainly accomplished by setting the two dynamometers at right angles in azimuth, but there is a residual mutual inductance, if only from the axial components of the coils, which at this short range fail to be represented by simple solenoids. As this residual influence would introduce a very appreciable error at heavy loads, with the sensitive differential adjustment, it is necessary to eliminate it, and this is done by single turn auxiliary coils, set by trial outside the instrument in such a manner as to possess compensatory mutual inductance be-between L and *u*, U and *l*, but no appreciable additional inductance tween L and *l*, U and *u*. All the leads to the instrument have to be carefully double wound to prevent external electro-magnetic influence. There are four windings on L, and also four on U, making eight pairs of binding posts in all for fixed coils, with two pairs of smaller binding posts for the connections with the suspended coils.

Coil.	No. of turns.	No. of layers.	Wire.	Resistance at 20 ohms C.	Inductance in millihenrys.
U 1	432	8	26 B.W.G.	7·11	5·44
U 2	120	4	22 ,,	0·934	0·588
U 3	28	2	15 ,,	0·0388	0·055
U 4	6	1	9 ,,	0·0028	0·023
L 1	120	4	19 ,,	0·36	0·389
L 2	28	2	13 ,,	0·22	0·052
L 3	4	1	strip 0·4″ × 0·02″.		
L 4	2	1	strip 0·875″ × 0·02″		

The control of these eight coils in any combination gives the instrument a very wide range, and it can be used to test any transformer of the ordinary type up to 100 kilowatt capacity.

The two small suspended coils are made of hard rubber and are similar. They have each an external diameter of 2·8 cms., internal 0·75, and an interflange of 0·96, wound with 675 turns in 27 layers of No. 33 B.W.G., with a resistance of 20 ohms and an inductance of 6·6 millihenrys. Each coil weighs about 30 grammes, and the weight of the whole suspended system is about 65 grammes. Four connections have to be permanently maintained with this system, one through the torsion wire, one through the damping vane, and two by single loops of fine copper wire 0·002in. (0·005 cm.) passing under the base from opposite sides of the suspension rod of hard rubber to small binding posts. These loops are so flexible that they do not sensibly impair the oscillatory freedom of the system within the small limit of play allowed. The insulation of these fine wires is carefully preserved by carrying them up the suspension rod imbedded with wax in little grooves. This is essential, as 2,000 volts may be active between them. The suspension wire is of copper 32·6 cms. long, and 0·0115 cm. in diameter. Its torsional moment is 18·6 centimetre-dynes per radian of twist, and one complete revolution of the torsion head can be allowed without sensible elastic fatigue. The zero of the instrument is read by mirror, telescope, and scale. A slight directional

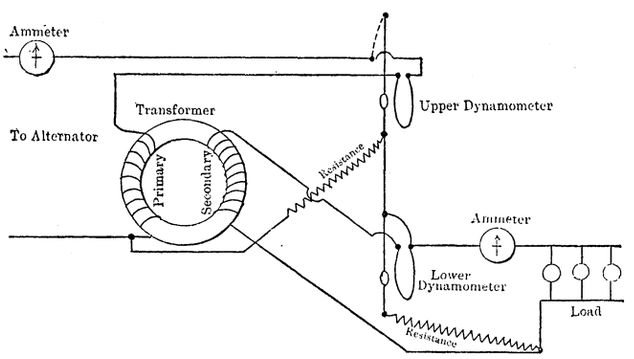
force is provided by two loops of wire from the vane head to the sides of the damping vessel, which wire loops, maintaining electrical connection between the vane and base terminal, are straddled by small rider weights whose gravitational influence is sufficient to keep the zero definite. The vane itself swings in water covered with a layer of heavy oil, so that the oscillations are almost dead-beat.

The transformer connections are indicated as shown in the accompanying figure. The compensation for mutual inductance between L u and U l, is first completed with each pair by trial. The two dynamometers are then balanced differentially. The fixed coils are connected in series and the suspended coils in parallel with suitable non-inductive resistances in their circuits, and these resistances are adjusted until balance is obtained. For 1,000 volts of alternating primary pressure, 20,000 ohms is a good resistance for the primary suspension circuit, and in the secondary whatever may be necessary. For 100-volt secondaries, 4,000 ohms can usually be paproximated to, making the C^2r loss in this circuit about 2·5 watts. The value of the torsion readings is then found for either dynamometer by trial.



When the connections are made, as in the Figure, and the secondary coil is open, the torsion needed to restore the zero is due to the upper dynamometer only, and measures the excitation loss. As the load is connected with the secondary, the torsion increases and measures the loss in the transformer plus the two or three watts absorbed in the circuit of l. If it is desired to analyse the loss due to hysteresis and eddies at each load, ammeter readings must be taken in both primary and secondary circuits, and in any case voltmeter and ammeter readings are required in the secondary circuit to determine the output. From this out put and the observed loss in the transformer, the efficiency can be immediately deduced. It is easy to show that with such an instrument the results are not influenced by the shape of the waves of E.M.F. generated by the alternator, and that the error due to lag in the suspended coil circuits is quite negligible when proper non-inductive resistances are employed.

The following is a specimen table of observations on a particular transformer. The calibration was so adjusted that each degree of torsion represented one watt. It will be seen that the loss due to hysteresis and eddies combined is practically constant throughout. In a few instances, tests of transformers whose magnetic leakage has been considerable, have shown an apparent decrease in excitation loss between idleness and full load, but amounting to only three per cent.

In this case the wattmeter was differentially balanced after compensation for mutual inductance and carefully adjusted.

Balance 19,480 ohms in primary suspension circuit.
3,735 ,, ,, secondary ,, ,,

These resistances were of bare German silver wire, non-inductively wound on insulating grids. The compensation and balance were checked after test.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 13th.

PHYSICAL SOCIETY.

5 p.m. Paper to be read: "Upon Science Teaching," by F. W. Sanderson, M.A.

SOCIETY OF ARTS.

8 p.m. Howard Lecture I. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

SATURDAY, January 14th.

ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.

11 a.m. and 2 p.m. Meeting at University College. Papers to be read: (1) "A Model Lesson on Geometry as a Basis for Discussion," by Mrs. Bryant, D.Sc.; (2) "The Use of History in Teaching Mathematics," by G. Heppel, M.A.; (3) "The Teaching of Elementary Arithmetic," by F. E. Marshall, M.A.

JUNIOR ENGINEERING SOCIETY.

2 p.m. Visits: To the Millbank Street and Eccleston Place Stations of the Westminster Electric Supply Corporation.

TUESDAY, January 17th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed:—"Gas-Power for Electric Lighting," by J. Emerson Dowson, M.Inst.C.E. After which a Reception will be held by the President and Council in the Libraries.

WEDNESDAY, January 18th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Annual General Meeting at the Institution of Civil Engineers. Election of Officers and Presidential Address by Dr. C. Theodore Williams.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Mining Industries of South Africa." By Bennett H. Brough, F.G.S.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Annual Meeting at 20, Hanover-square, W. Presidential Address by Dr. R. Braithwaite.

THURSDAY, January 19th.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Papers to be read.

FRIDAY, January 20th.

SOCIETY OF ARTS.

8 p.m. Howard Lecture II. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse:—"Liquid Atmospheric Air," by Prof. Dewar, F.R.S

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Hopkinson Three-Wire Patent.—Judgment in the action Hopkinson *v.* St. James and Pall Mall Electric Light Company will be delivered by Mr. Justice Romer on Saturday morning next.

ELECTRICAL SUPPLY IN LONDON.

The progress of electrical supply in London during the past year is for the present to be estimated by the increase in lamp connections rather than by new mains laid. We say for the present, for the real measure will not be forthcoming until the accounts are made up and published. According to the table we printed as a supplement to our last issue, the total lamp connections in 8 c.p. amounted to 503,902, as against 179,060, in December, 1891, according to Mr. FRANK BAILEY'S estimate, showing an increase of 324,842 in about two years. We propose to analyse some of the figures given in our table, for the purpose of elucidating some points in the nature of the demand and in the provisions which exist for meeting it.

The maximum load observed during 1892 in the case of the Eccleston Place Station of the Westminster Supply Corporation, was only 25 per cent. of the possible demand. Of the other companies the Kensington Court Station of the Kensington and Knightsbridge Company shows the low figure of 27·8 per cent., and it thus appears that, in purely residential districts, only about one-quarter to one-third of the lamps connected are turned on at the same time. On the other hand, those companies which are fortunate enough to number theatres and clubs among their consumers, find that the proportion runs up to one-half, as in the case of the St. James-Pall Mall Company, and 53 per cent. in that of the Electricity Supply Corporation. After all the troubles of the London Electric Supply Corporation they have, at all events, succeeded in getting the best class of consumers, who, at one time, burned 58½ per cent. of their whole number of lamps. The average of all the London companies was 40 per cent., excluding St. Pancras Vestry, from whom we have been unable to obtain the necessary information.

We have alluded to the total number of lamps connected as representing the total possible demand. It has been customary to suppose that the plant capacity of a station ought to be sufficient to meet this demand at half-an-hour's notice; and in discussing the vexed question of the methods of charging it has been suggested that when a consumer connects a hundred lamps in his house, there ought to be enough plant, allocated to him as it were, at the station, to run these lamps if required. The demand that a bank should hold sufficient bullion to meet its notes in circulation would be much more reasonable. On the other hand, few, if any, of the London central stations are running "full," and, with one or two exceptions, they could all meet the maximum possible load, as far as their engines and dynamos are concerned, though we doubt if the boilers of a majority of stations would be equal to the task. One acknowledged exception is that of St. Pancras Vestry, where, if we are rightly informed, the lamp connections, estimated in 8-c.p. lamps, exceed the plant capacity 20 per cent. The House-to-House Company have lamp connections equivalent to 92 per cent. of their plant capacity, and the Chelsea Company 87½ per cent. This last, relying as it has done to a large extent on secondary batteries, would probably be unable to stand a long "run" on its resources. The St. James-Pall Mall Company, like the St. Pancras Vestry, have 20 per cent. greater lamp connection than plant capacity, but their new station in Carnaby-street is nearly completed, and, with the additional plant, the proportion will be reversed, and will come down to about 80 per cent. The Metropolitan Electric Supply Company, as we learn since last week, has a plant capacity equivalent to 240,000 eight-candle lamps. Of this, the lamps connected come to 52 per cent. At the other end of the scale, St. John's Wharf, Westminster, comes lowest with 31·6 per cent., and Deptford next with 33 per cent. Taking the average of thirteen, the lamp connections come to 68·2 per cent. of the plant capacity. The grand total of 503,892 lamps connected is 59 per cent. of the grand total of 852,000 plant capacity; this, by the bye, is equivalent to about 40,000 horse power.

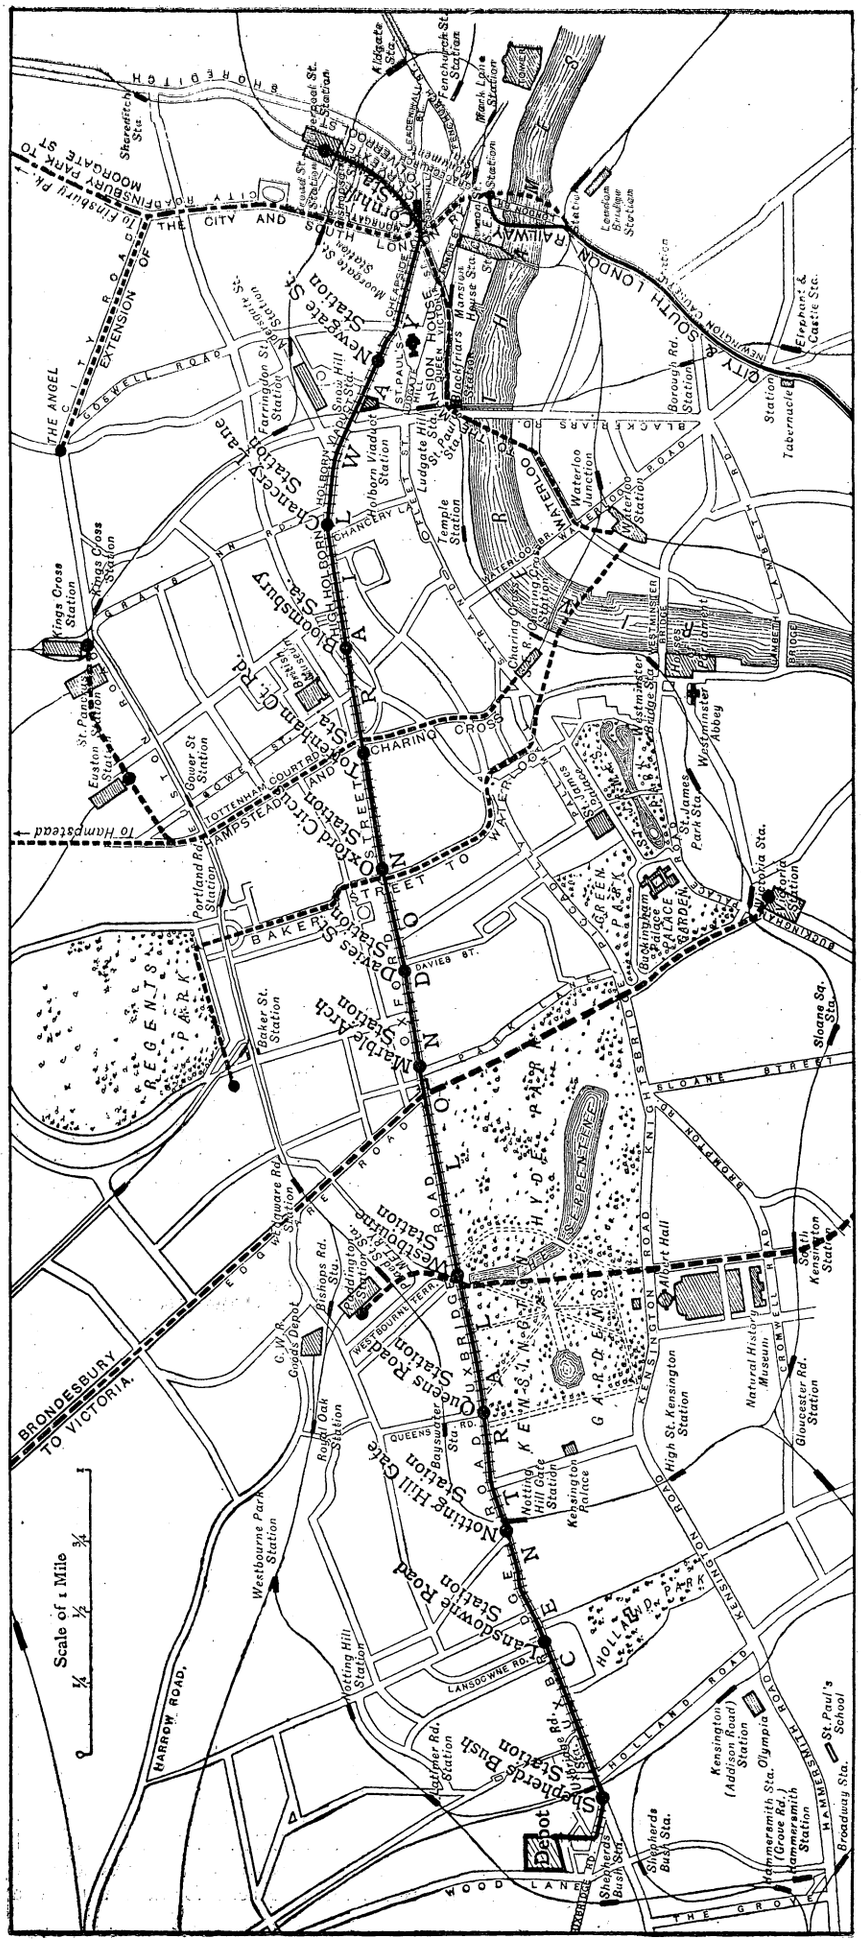
Turning to actual facts instead of possibilities, we find that the nearest approach to a "run" last year was experienced by the St. James-Pall-Mall Company, who used 62 per cent. of their plant to provide the maximum observed load; but the same demand, when their new station is started, would employ only 48 per cent. The House-to-House Company comes next with 40 per cent., and Deptford with 39 per cent. The lowest is the St. John's Wharf Station with 12·1 per cent., but a considerable portion of the plant at this station is destined for the lighting of some large buildings which are not yet fitted. The average of eleven stations, according to the figures given in our supplement, comes to 27·3 per cent. The margin of 72·7 per cent. in the present plant capacity must not, of course, be regarded as a reserve, but as a provision for future consumers. The proportion of reserve or spare plant which will be actually required when the stations become fully loaded need not at present be considered. It is not probable that the overloading of the old Grosvenor Gallery plant will be repeated in any of the existing stations. The margin, such as it is, while an admirable security for the consumers, is not to be regarded with equal favour by the shareholders, since interest and depreciation continue to run whether it is used or not. In some cases the plant capacity given in our table probably represents the ultimate capacity of the station rather than the actual generating machinery in working order.

Not only is electric supply burdened for the present with spare plant, but a large expenditure of capital for mains in the streets has been incurred, and this is only partially utilised. The coloured map which forms the supplement to our present issue shows with what energy the supply companies have spread their network over the metropolis. The increase of business during the last year is to be found, as we have said, in the lamp connections rather than in the mains, and as a comparison between the present map and the one we published on January 15th of last year shows that, as no great number of new streets have been opened, there is good reason to suppose that the financial result will be better, the increased lamp connections having been made to the existing mains. The private lighting in the City is the chief addition to our map, but we regret that we are unable to give any particulars about the progress of the work. The City was divided into three districts, two of which were secured by the Brush Electrical Egineering Company, and one by the Laing, Wharton, and Down Construction Syndicate. The first two, now merged into one, are shown by the vertical blue ruling; and the third by horizontal ruling. The street lighting in the City, as in St. Pancras, is carried out by a special service of mains, which, by order of the Board of Trade, is kept distinct from those for private supply. Having extended our map eastwards, we are able to show some of the South London work of the London Electric Supply Corporation. The only considerable extension compared with last year is the advance of the Notting Hill Company into the Campden Hill district. This Company, we believe, like the St. Pancras Vestry, was a little too generous at first with its mains, and laid them in streets in which but few customers could be found. A demand then arose elsewhere, and more mains had to be laid. In connection with our map, the density of the lamps per mile of main is interesting. The happy St. James Pall-Mall Company leads the way, as might be expected, with 6,400 lamps per mile, or one lamp to less than 10in. of main. The Metropolitan Company comes last, with only 630 lamps to the mile, or about one to every 8ft. 6in. of main, and the House-to-House Company next, with 885. The Kensington and Knightsbridge, cheek by jowl with the latter, has 3,700 lamps per mile; the only other high figure, and one that is rather surprising, being St. Pancras with 4,360. A singular difference exists between the averages of the nine companies who have furnished us with their length of mains, and the ratio of the grand totals. The companies average 2,380 lamps per mile, but the 498,892 lamps (that is, excluding the 5,000 of St. Luke's, Chelsea) over an aggregate of 452 miles, 198 miles of the Metropolitan Company being added to those given in our table, comes to 1,100 lamps per mile.

ELECTRIC RAILWAY SCHEMES IN PARLIAMENT.

Possibly, it may be premature to call all those underground lines which have been projected "electric railways," but there seems to be a choice only between cables and electricity; and, while we are prepared to admit that cable traction may be the most serious rival of the electrically propelled car, it is likely to compete seriously only on lines with heavy gradients and with an irregular traffic. Six Bills for new underground lines were referred in March last to a joint committee, which reported strongly in favour of the Greathead system of tunnel construction, of electric traction under ordinary circumstances, and of cable traction for steep gradients. The report, which was printed in *The Electrician*, Vol. XXIX., p. 103, recommended that, as the schemes were satisfactory as instalments of yet larger proposals, the Bills should be sent forward in the usual way.

Hosted by Google



PROJECTED ELECTRIC RAILWAY SCHEMES.

The following lines were proposed:—

	Miles.
The Great Northern and City Railway	3¼
The Central London Railway	6½
The City and South London Railway (extension)	2¾
The Waterloo and City Railway	1½
The Baker-street and Waterloo Railway	3
The Hampstead, St. Pancras, and Charing-cross Railway	5¼

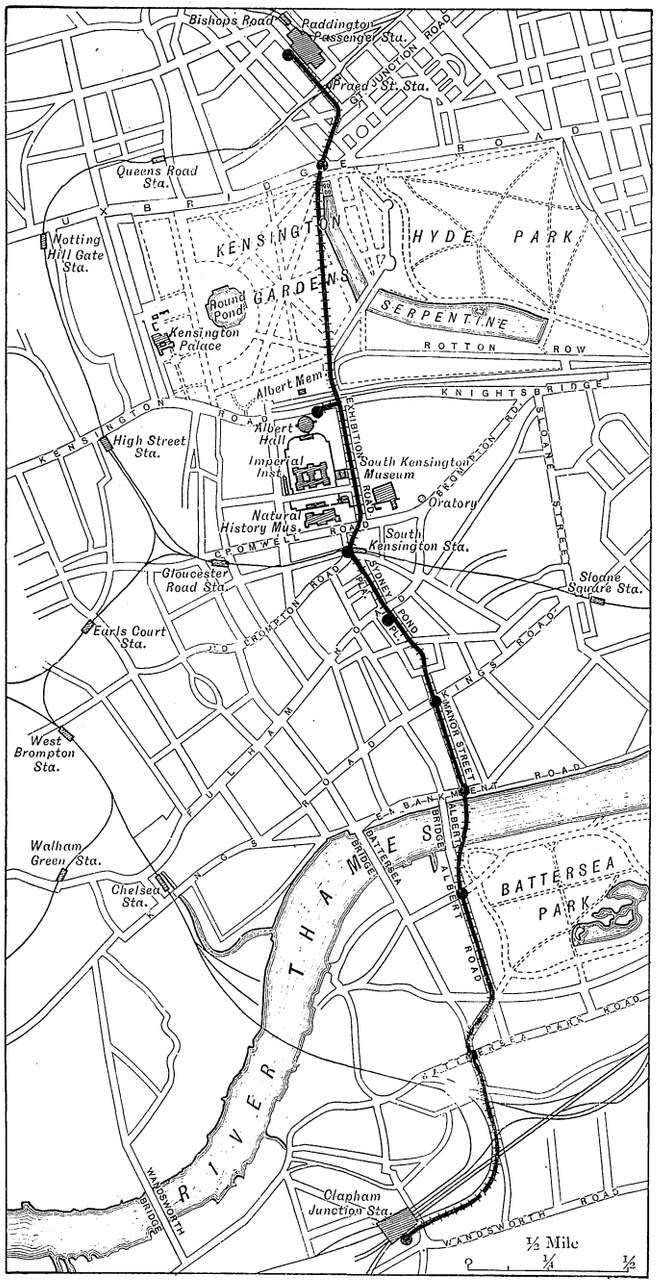
The proposed routes were clearly shown in a map published in *The Electrician*, Vol. XXVIII., p. 252, and herewith we print two maps, the one showing the above lines, together with the latest proposals, viz.:—

	Miles.
The Edgware-road and Victoria Railway	4½
The Clapham-junction and Paddington Railway	4½

the latter being also shown complete and in more detail on a separate map. We understand that the Charing-cross and Hampstead line is the only one of the eight not intended, for the present, to be worked by electricity. Of the six Bills of last year those of the Great Northern Railway and of the Central London Railway alone succeeded in passing, the remaining four being left by the late Parliament in different stages of development.

The schemes at present before us may be divided into two classes, lines which are intended to feed or to form extensions to or connection between existing railways, and lines which are intended to relieve, or, indeed, to compete with, that class of traffic which the daily Press is wont to call vehicular. The former being promoted in most cases by the railway companies will probably be financed by them in the usual manner. All the Bills have met, and will meet, with considerable opposition. The Paddington and Clapham line will be recognised by our readers as a development of the proposed subway from Paddington to South Kensington. The impudent attempt to drive a "cut and cover" line across Kensington Gardens, the actual staking out of the route on the grass, the threatening of disastrous disturbance to the laboratories on either side of Exhibition-road, and the complete victory of public and scientific opinion, have not be forgotten. The line was intended as a feeder to the Albert Hall, and was promoted by friends of that institution. The scheme comes forward again in a new shape, and with much more promise of usefulness. We do not, however, believe that the sinking of the line to a depth of 70ft. will

Hosted by Google



Route of Proposed Paddington and Clapham Junction Line.

alleviate the disturbance to the laboratories, and the professors, as well as the important bodies who govern their colleges, will, of course, renew their opposition. The inhabitants of river-side Chelsea, utterly without railway communication, will, of course, welcome the scheme; and the constituents of the member for Battersea will, no doubt, look favourably on it.

The Central London Railway, though giving access to a branch of the Great Western and other lines at Uxbridge-road Station, and, according to the proposed extension, to the Great Eastern and London and North-Western at Broad-street, may be considered a private line. So far as we have heard, the public have not been invited to subscribe capital for this most important railway, and there is every reason to suppose that it will fall into the hands of modern financiers, if indeed it has not stuck there ever since the day on which Royal assent was given to the Bill. The discussion of particular financial transactions is quite beyond our province, but the electrical industry has already suffered so much, and is likely to again at the hands of the greedy middlemen who pretend to assist it by their artifices, that we may for once depart from our usual custom so far as to discuss principles.

Not long ago, a scheme such as the Central London Railway requiring some two and a quarter millions, would have been offered to the public for subscription, and we now learn that "arrangements are being made with a leading house for a capital issue early in the new year." But before recourse was had to this leading house, whatever it may be, and if indeed the report be true, attempts were made to promote this line on modern principles. Certain systems of underwriting, of founders' shares and other tricks, which would not long ago have been denounced in any court of justice, have apparently been legalised by the Limited Company Acts. An Act acquired for any considerable undertaking is regarded to-day not as powers to do certain work, but as a "concession" to be bought and sold as often as possible, each successive buyer being regarded by the vendor as a bigger fool than the last—that is, himself. Eventually the work has to be done by somebody, or the money is lost—as in the early Niagara schemes—or abandoned, as at Panama. The "handsome" bonuses paid to concessionnaires are simply mulcted from the public, and lost to the electrical industry; not a soul but the speculators, granting that they are thus spiritually equipped, being the better for them This system may be well adapted for republics, but so far from assisting industrial enterprise in this country, we believe that a return to the old-fashioned systems, on old-fashioned principles, by men of old-fashioned morality, would lead to some of the old-fashioned genuine successes, upon which the greatness of England has been built.

THE POST OFFICE TELEPHONE.

In our issue of September 2nd last we published the text of a circular issued by the Postal Telegraph Administration on the subject of telephone circuits, which included a diagram showing the connections of a new arrangement of apparatus adopted by the Department to supersede the Gower-Bell telephone which has been employed so long, and with such good results. We are now enabled to furnish our readers with a description of the new instrument itself, which may be of interest.

It has been consistently maintained by the Postal officials that amongst the large number of telephonic instruments experimented with (which included all the principal combinations used in this country and abroad) the Gower-Bell transmitter and Bell receiver furnished the elements for constructing an instrument which should combine the maximum of efficiency and simplicity. Such an arrangement would constitute an apparatus suitable alike for use upon the shortest indoor telephone circuit, or for speaking over the longest line upon which it is at present practicable to converse. The transmitter arranged by Gower is, as is well known, an adaptation of Prof. Hughes' pencil microphone, eight carbon pencils being employed and arranged radially between supporting blocks fitted rigidly upon a pinewood diaphragm. This transmitter is entirely devoid of adjustment, and has stood well the test of time. Since its adoption by the Post Office it has undergone several modifications in detail, by which the articulation has been rendered much clearer than was the case with the earlier form. A distinct improvement was effected by covering the diaphragm with a board, in the centre of which a mouthpiece of porcelain was fitted, for the purpose of directing the sound waves of the speaker's voice upon the middle of the diaphragm, where is fixed the principal carbon block supporting one end of each of the eight pencils. Porcelain was selected as the material from which to construct the mouthpiece, as it afforded a good glazed surface, easily kept clean, and not affected by the breath, as is the case with wood coated with varnish or French polish. It was soon found, however, that the breath condensed upon the cold surface of the porcelain, and where the instruments were extensively used, moisture was formed, which found its way to the internal parts, and gave rise to troublesome faults. The advantages gained were thus to some extent neutralised, and in the new instrument the mouthpiece and board covering the diaphragm have been dispensed with, but the Gower-Bell transmitter has been retained. The dimensions of the diaphragm have been reduced to 7in. × 4¼in. It is held

Hosted by Google

in position between india-rubber supports (see Fig. 1), the object of these being to intercept the transmission to the diaphragm of external vibrations which may affect the wooden case of the instrument. The carbon blocks supporting the pencils are fitted to the diaphragm by means of small brass bolts passing through both the diaphragm and the blocks, and tightened by a small nut on the lower or inside end of each bolt. The heads of these bolts are left projecting above the surface of the diaphragm, with the object of preventing its being temporarily employed as a desk for writing down communications. This practice was commonly resorted to in the earlier forms of the Gower-Bell instrument, with the result that the flexure of the diaphragm resulting from the pressure exerted in writing broke the pivots of the microphone pencils, the transmission was interfered with, and many other faults were occasioned.

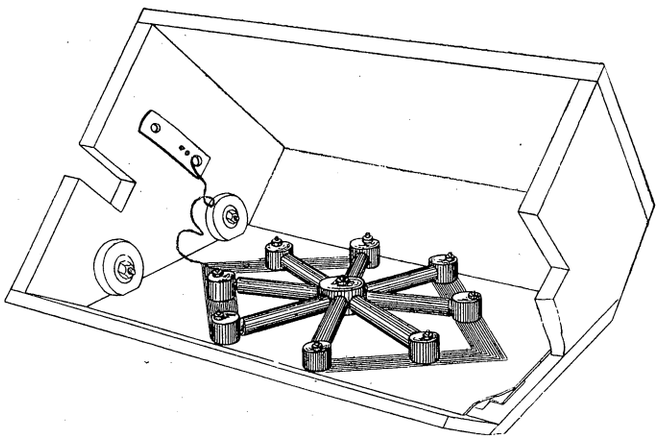


FIG. 1.—View of cover of New Post Office Telephone showing Gower microphone and diaphragm held in position between india-rubber supports. When the cover is placed on the telephone the microphone is uppermost.

The induction coil has also undergone some modification. It is well known that the presence of the secondary winding of the induction coil at the receiving end of a telephone circuit is distinctly prejudicial. Many attempts have been made to operate the telephone with this coil short-circuited when receiving, and by means of such devices conversation may be rendered possible on lines where it would otherwise be impracticable. The Post Office operators' telephones have for some years been provided with a press button inserted in the handle of the instrument, by depressing which the clerks may, in any case of difficulty in hearing, short circuit the secondary winding of the induction coil, and so increase the volume of sound from the receiver. The manipulation of such an arrangement requires a nicety of judgment and precision of movement which it has been shown cannot be expected from the ordinary user of the telephone, and the general application of the arrangement is, therefore, impracticable. In the Post Office telephone the next best condition favourable to the listener has been provided for by winding the secondary wire of the induction coil to a resistance of 150 ohms. It has been ascertained by experiment that this resistance represents the minimum number of convolutions with which satisfactory results for general working can be obtained with the gauge of wire usually employed for winding the coils. The resistance of the primary winding remains as before—·5 ohm.

Probably the most defective element of the Gower-Bell telephone was to be found in the india-rubber hearing tubes. These deteriorated more or less rapidly, according to the position and surroundings where the apparatus was employed. The effect of a cracked tube is to reduce the efficiency of the receiving portion of the apparatus in a surprising degree, and the renewal of the tubes was a somewhat expensive item in the maintenance of the instruments. So soon as the Bell telephone patent had expired the Postal Telegraph authorities therefore determined to abandon the use of the hearing tubes, together with the Gower-Bell receiver, and to employ in their place two Bell receivers. This change is being gradually effected as the india-rubber tubes become faulty. The Post Office telephone is similarly equipped with a pair of Bell receivers. They are of the double-pole type, which has of late so largely supplanted the older single-pole instrument, and is an adaptation of that originally introduced by Messrs. Siemens and Halske, of Berlin, and described in Preece and Maier's work on the telephone (page 54). The modern form has an external appearance similar to the single-pole instrument, and is manufactured by several English firms. When used in conjunction with a Gower-Bell transmitter, the efficiency of the combination is about 10 per cent. greater than that of the complete Gower-Bell apparatus. The electromagnetic inertia is minimised, and the discharge of the line facilitated in the new telephone by connecting the receivers in multiple. The resistance of each is about 120 ohms.

The employment of "French" terminals with the Bell receiver has become very general, but they have the drawback that some special form of fitting has to be attached to the ends of the flexible connecting cord, in order to ensure a reliable contact between the latter and the terminal. The Post Office department, however, employs a special terminal upon its Bell receivers (see Fig. 2), designed to admit of the use of ordinary

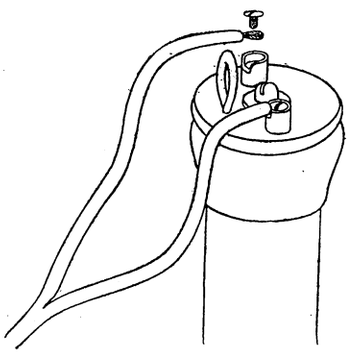

FIG. 2.—Special Post Office Terminal for Bell Receiver.

cord without the usual prepared ends, and to facilitate the renewal of worn out or broken cord ends. The upper end of the terminal is recessed to receive a connecting screw, and a carefully rounded groove is cut in one side to admit of the insertion of the conductor cord. The covering of the latter being removed, the bare conductor is inserted beneath the connecting screw, which is firmly screwed down. Should the conductor break or wear it is only necessary to strip back the covering and effect a new connection. Pillars provided with a similar connecting screw are fitted inside the case of the instrument to receive the cord

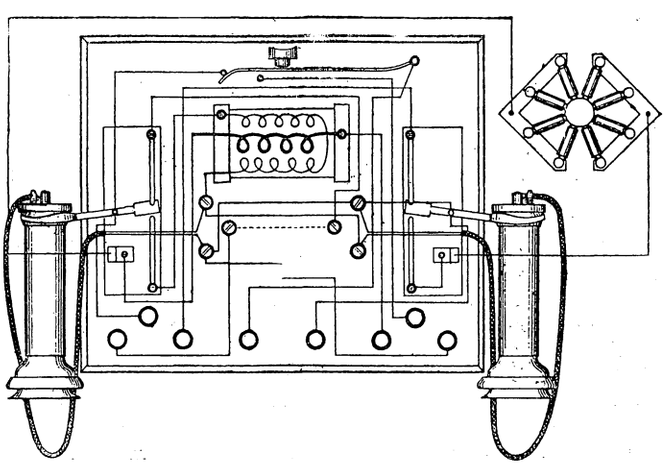

FIG. 3.—Diagram of Connections of New Post Office Telephone.

ends and the connecting wires from the relay coils. The arrangement is simple and economical, and seems well suited for its purpose.

The complete instrument appears to combine the maximum of efficiency with extreme simplicity of parts, and we understand that it has been satisfactorily employed for some considerable time at the offices of the various firms who rent

Hosted by Google

private wires to the central switchboard at the General Post Office for speaking to Paris.

Eight terminals (see Figs. 3 and 4) are provided for receiving the external connecting wires, and the instrument can thus be used interchangeably with the Gower-Bell. The object of having so many outside connecting terminals is to enable the apparatus to be employed either upon a simple telephone line, at an intermediate office in conjunction with a switch, at an exchange, or at an ordinary subscriber's office, without altering the internal connections. It is only necessary to furnish each workman with a set of diagrams illustrating the various combinations of external connections which are required to meet the varying conditions under which the instruments may be employed. There is no case where all the terminals are in use together, but it will be obvious that many advantages will apply to an instrument of such universal application.

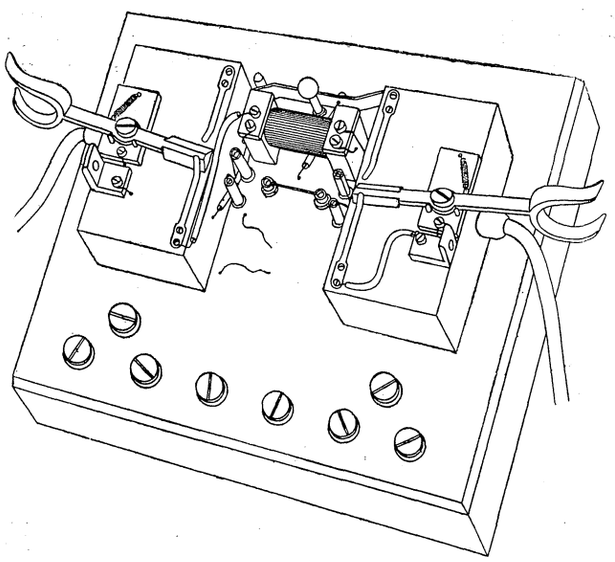

FIG. 4.—Perspective View of New Post Office Telephone with lid removed.

To suit the convenience of those who desire to have the telephone placed upon a desk or table in front of them, a table-stand is provided when desired. The telephone is fitted upon one side of the stand, and the opposite side is utilised for fixing the call bell. The permanent line and battery wires are connected to a tablet having seven terminals, fixed in a convenient position upon the desk or table, and a similar tablet is fitted to the table-stand. Between these two tablets a flexible connecting cord, composed of seven conductors, is inserted, and this cord enables the user to move the apparatus into any position where it may be desired to place it upon the table.

GAS POWER FOR ELECTRIC LIGHTING.*

BY J. EMERSON DOWSON, M.INST.C.E.

The author stated that in Great Britain alone gas-engines had been sold for electric lighting exceeding, in the aggregate, 7,000 H.P., and that in Germany engines were used for about 1,100 arc and 90,000 glow lamps. It was, however, only within the last few years that gas-engines of large size had been before the world in a practical form. The varying load-factor in central stations was a serious trouble, and the author hoped to show that much of the present loss due to fuel, water and wages, would be avoided if gas power were used instead of steam power.

Special reference was made to the central station at Dessau, belonging to the German Continental Gas Company. That station was opened in 1886 with two 60 H.P., one 30 H.P., and one 8 H.P. (effective) engines, worked with town gas, and all the dynamos were driven by belting and counter-shafts. In 1891 considerable alterations were made. One 60 H.P. engine, with its belting and counter-shaft, was retained, and one of 120 H.P. introduced, coupled direct to its dynamo. The speed of the engine and coupled dynamo was 145 revolutions per minute, and the consumption of town gas was equal to 39 cubic feet per kilowatt-hour. Formerly, without accumulators, it was thought necessary to adjust the size of the engines to the supply, so that they should always be worked to their full extent. It had, however, been found that a limited supply could be more advantageously furnished entirely from accumulators. In spite of the loss of about 21 per cent. in the accumulators, large engines worked more profitably in parallel than smaller ones supplying direct without accumulators. Since February, 1889, the Municipality of Schwabing, a suburb of Munich, had used an Otto engine worked with Dowson gas for 10 arc and 300 glow lamps. The load was variable, but, with an average output of 22·5 kilowatts per hour, the fuel consumption was 3·3lb. per kilowatt-hour. The town of Morecambe was lighted by nine arc lamps and glow lamps, equal to 1,600 of 8 c.p. each, the dynamos being driven by Stockport gas-engines worked with Dowson gas. With an output of only 1,155 kilowatts per week the consumption of fuel was 2·58lb., and the cost of the gas, including wages and fuel, was ½d. per kilowatt-hour delivered. At the *château* of M. Say, at Longpont, in the south of France, there were 650 glow lamps and on arc lamp, supplied by a dynamo driven by a Crossley engine worked with Dowson gas. The consumption of fuel was 1·2lb. per I.H.P. hour, and 2·7lb. per kilowatt per hour.

It was believed that the late Sir William Siemens first drew attention to the fact that, when illuminating gas was burnt in a gas-engine to drive a dynamo, much more light was produced electrically than could be produced by burning the same quantity of gas in burners in the usual way. Latterly the consumption of gas per H.P.H. in gas-engines had been reduced, and the ratio was at the present time about 20 to 1 in favour of converting the gas into an arc-light by means of a gas-engine. The author had collected data from various sources as to the consumption of ordinary town gas by engines supplying electric light, with and without accumulators. The average of all the returns, with engines under varying loads and without accumulators, was about 47 cubic feet per kilowatt-hour; when accumulators were used the consumption of gas was less, because the engines then worked under a full load. With 47 cubic feet per kilowatt-hour, and 55 watts per 16 c.p., one light of that power required only 2·6 cubic feet per hour; whereas a standard Argand burner required 5 cubic feet per hour. In this comparison it was assumed that the glow-lamps and gas-burners were in good order; but, unde ordinary working conditions, they did not maintain so high a duty.

The question of load-factor was a serious one with any type of engine, but with gas-engines the loss was much less than with steam-engines. When a gas-engine was stopped, its consumption of fuel stopped also, and there was no furnace to maintain; nor was there any water to boil at starting. At the same time, it was desirable that the gas-engine should be worked as much as possible under a full load, and in this respect the experience at Dessau was generally confirmed. A central station was worked under trying conditions, and in the London district there was only a full output of current during from three to five hours in every twenty-four; moreover, about 60 per cent. of the total output was required during that short period. In practice, this meant that in a station where the current was supplied without accumulators, the engines were run at a reduced speed during a portion of the time, and at other times some of them were stopped altogether; but all had to be ready to work in the evening, and occasionally in the day-time when there was fog. Generally, it might be assumed that the average consumption was more than 6lb. per kilowatt-hour where accumulators were used, and about 9lb. to 12lb. where they were not used. In any case, with the best possible arrrangement of steam power, there must be a large amount of fuel consumed which did no useful work; for, even if some of the fires were drawn, they had to be re-lighted, and the large quantity of water which had cooled during the time of standing must be re-heated.

The author believed that the solution of the difficulty was to be found in the use of gas plant instead of steam plant. With a large gas-engine, 1 B.H.P. per hour could be obtained with a consumption of 1lb. of anthracite, or 1½lb. of coke; whereas the consumption of coal with the steam-engines used for central stations, must be taken at about 2½lb. per B.H.P., when working under a full load. A saving of not less than 50 per cent. could therefore be effected in stations where the engines were fully loaded; and, where there were great fluctuations in the output, the loss of fuel with boilers not used, or only partly used, could be almost entirely avoided. For a maximum output of 400 kilowatts, there would be three gas generators, each capable of supplying one-third of the maximum required. The production of gas could be raised or lowered in several ways, and the working of each generator could be stopped immediately, by shutting off its steam supply. Supposing, therefore, that all three generators were working at their maximum rate, and a gradual reduction was

* Abstract of a Paper read before the Institution of Civil Engineers on Tuesday last.

Hosted by Google

required, this could easily be effected; and, when the production of one or two generators could be dispensed with, their operation was at once stopped. The third generator could then be kept at work, and its production adjusted to suit the minimum consumption required. A gas generator had a small grate area compared with that of a boiler, and much less cooling surface; it contained no water, and required no chimney draught. A generator of the size referred to lost only 6 to 8lb. per hour whilst standing. If an average of only 40 per cent. of the maximum power were required for 21 hours, it was equivalent to letting two of the generators stand for that period; and at 8lb. each per hour that meant a total loss of only 3cwts., compared with the much greater waste when steam power was used. As the use of large engines, driven with generator gas, was of recent date, the author proceeded to describe the gas plant used, and gave the results of engines working regularly with Dowson gas, under the usual conditions obtaining in factories. He also gave the results of brake-tests made with several engines of large size, and reproduced indicator diagrams taken from engines of different makers. Although admirable results had undoubtedly been obtained from engines working with the Otto cycle, he was of opinion that, with engines of large size, the results would be still better if the cycle were altered, especially when generator gas was used. His reasons for this were fully stated in the Paper.

The following was a summary of the points urged by the author:—1. When town gas was used for driving the engines of an electrical station, the consumption was about 50 per cent. less than the volume of gas required to give the same amount of light by ordinary burners. 2. When town gas was used, neither boiler nor firemen were required, and there were no ashes to remove; less space was needed; no accumulators were required, except such as might be necessary to equalise the load of the engines, and to provide for a small amount of storage. The engines could be worked in the most crowded districts, close to where the lights were required, and where boilers were not allowed. 3. When generator gas was used, the consumption of fuel under a full load would be at least 50 per cent. less than with steam power, and the loss due to steam-boilers not being fully worked could be almost entirely avoided.

THE ELECTRIC LIGHTING OF KINGSTON.

As the proceedings at the last meeting of the Kingston Town Council possessed several features of more interest than is usual when electric lighting matters are discussed by local authorities, we think the following summary may not be without its value:—

The minutes of the Electric Lighting Committee stated that Mr. Preece had attended and given the Committee the benefit of his experience gratuitously, as a neighbour. Mr. Preece strongly advised the Corporation to establish electric lighting in the Borough, both for public and private purposes, and to keep the work in their own hands. He considered that after the works had been fairly established they would pay, and be no burden on the ratepayers. He considered that the price to be charged for the supply should be 6d. per unit. He recommended that instead of the Corporation deciding upon any particular system of electric lighting, they should advertise for tenders, which would bring tenders from the various firms, who would specify how they proposed to supply what was required. It would then be necessary to compare the tenders, and select that found most satisfactory. He considered that if the matter were at once proceeded with the Corporation would be in a position to supply electricity to the County buildings by September next.

It was thereupon resolved that the Council be recommended to authorise this Committee to obtain tenders for the purpose of supplying electricity for 5,000 private incandescent lamps and also to 30 or 40 arc lamps for street lighting in accordance with a specification to be prepared on the lines suggested by Mr. Preece, also to authorise the necessary steps to be taken to obtain the sanction to the borrowing of £16,000 for the above purposes.

The ex-Mayor said Mr. Preece had been preparing a specification for Tunbridge Wells, and he believed that with slight modifications it would answer for Kingston, and he had kindly said that he would send it to them when ready, and give them the opportunity of using it if they were so disposed. The Mayor, the Town Clerk, and himself went down to Oxford a few weeks ago, in order to see the installation there. They were struck very much by the fact that High-street, Oxford, was lit by electricity for part of its length, and for the other part by gas. Standing at the junction of the two systems they could see in a moment the immense superiority of the electric light, and therefore they were led to take Mr. Preece's recommendation in a spirit they would not otherwise have done. Mr. Preece was of opinion that within three years the light would pay as a commercial undertaking, and that subsequently there would be a profit applicable to the reduction of the rates. This had been borne out by what had occurred at Bradford. If Richmond, Surbiton, and other neighbouring districts were going to be lighted by electricity, it would not do for Kingston to lag behind. Therefore, he heartily commended the resolution in favour of borrowing £16,000 to the Council.

Councillor Baker moved, as an amendment, that "Inasmuch as the information before the Council as to the success of the electric lighting in other towns similar to Kingston is so meagre and unsatisfactory, and that so few householders in the Borough are likely to take the light if provided, it is unwise and inexpedient for the Corporation to apply to the Local Government Board for a loan of £16,000 to be used in experimenting in lighting part of Kingston with the electric light. Councillor Baker called in question the figures of Mr. Shoolbred, contending that he had not allowed enough for working expenses, and had over-estimated the probable consumption of the light by private customers. In order to make the receipts balance the outlay Mr. Shoolbred took credit for 5,000 8-c.p. lamps. He wanted to know how that estimate was arrived at, and he was told by the ex-Mayor that it was based on the experience of other towns. He asked for the names of the other towns, but he could not get them. Mr. Preece mentioned Eastbourne and Brighton; but where was the reason or fairness of comparing those places with Kingston? Then Mr. Preece wound up with the suggestion that wherever local authorities had taken up the matter it had been a success; but the only instance given by the ex-Mayor was Bradford, which it was absurd to compare with Kingston. He thought they would find very few customers for the electric light in houses rated under £40. In Kingston there were 5,434 houses, of which 4,074 were under £20, and 4,842 under £40. That did not leave much margin for private consumers. He alluded to Taunton, which was nearly the same size as Kingston, where they had found the electric light a heavy burden. He contended that it would be a losing game, and that it was a luxury which very few people could afford to pay for. No doubt he should be told that if they did not do it they would have a company come in and do it. He did not object to that, because then anybody who wanted the light could have it, and there would be no burden on the rates. There were many places where companies had been allowed to supply the light. Their debts were increasing by leaps and bounds, and he should like to ask the Chairman of the Finance Committee to say what was the present indebtedness of the Borough, so that they could see whether there was any possibility of borrowing the money if they made this application to the Local Government Board, or whether they had not already exceeded their powers.

Councillor Walker said the present financial position of the Corporation was that they owed £63,578 on loans, the repayment of principal and interest on which would require a rate of 10d. in the £. If they borrowed for electric lighting, &c., the total debt would be brought up to £93,578. If all the proposals involving expenditure were carried out the indebtedness of the Borough would be brought up to £131,078, to meet the repayment of which would necessitate a rate of 1s. 6d. in the £. The rateable value of the Borough was £125,000.

Councillor Selway suggested that the recommendation set out in the minutes needed transposing. It was useless to ask for tenders until they had obtained consent to borrow the money. If they obtained tenders, and the Local Government Board seeing the state of their finances should refuse to allow them to go into this experiment, then all their trouble and expense would be thrown away. He did not think there was a sufficient demand on the part of the public of Kingston for the light, and he thought the Committee would have been wise if they had canvassed the principal inhabitants and ascertained whether they would be prepared to take the light if the Corporation provided it. He thought it was a very risky thing to borrow £16,000 for a scheme until they knew what they were working upon.

The ex-Mayor, replying, said that with regard to the objections of Councillor Baker, Mr. Preece told them that the experience of other places was that the number of lights applied for was usually equal to half the number of inhabitants. The population of Kingston was 28,000, so that in fixing upon 5,000 lamps they were well within the mark.

For the amendment only five voted, and the motion was then agreed to.

Electric Traction at Milwaukee.—Numerous breakdowns and stoppages are stated to have occurred during November at the power-house of the Milwaukee Street Railway Company, and to have given rise to differences between it and the General Electric Company, the contractors, which have culminated in the termination of their business relations.

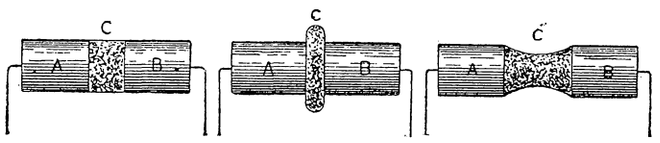
THE CLAMOND MICROPHONE.*

For the last twelve years so-called new microphones have been appearing, all of which, however, have involved contacts of unyielding carbon, the resistance of the contacts varying under the influence of the sound-waves. This form of microphone, nevertheless, has the inherent defect of permitting only sounds of medium intensity to be transmitted, since if the pressure at the points of contact is slight, the instrument is too sensitive, transmitting feeble sounds, louder ones only causing crackling due to ruptured contacts; whilst if the pressure is greater, the instrument is no longer sufficiently sensitive, and the speaker is obliged to shout. To overcome this, constructors have endeavoured to gain a *juste milieu* by carefully adjusted regulation. The aim of M. Clamond has been to avoid all necessity for adjustment. He has gone back on previous experience, and has abandoned the loose contact of unyielding carbon, substituting for it a plastic elastic body, the *shape* of which alters under the influence of the impinging sound waves.



The Clamond microphone (see Figure) is composed of a paste made by mixing some fine conducting powder with a viscous non-conducting liquid. This paste C is placed between two carbon rods A B connected with a diaphragm, and is deformed in the manner depicted, by the action of the voice. Experiments made are said to show that a microphone of this type has a wide range of action; that is to say, it transmits with equal facility words softly and loudly spoken, strident noises and violent explosions. It is also claimed that the Clamond microphone is outside the Berliner patent, and should, therefore, meet with a warm reception in the United States.

ANALYSES OF ELECTRIC SUPPLY IN LONDON.

The following figures have been calculated from the table published with our last issue, and are alluded to in our leading article this week.

—	Max. observed load. Lamps connected.	Lamps connected. Plant capacity.	Max. observed load. Plant capacity.	Lamps connected per mile of main.

LEGAL INTELLIGENCE.

National Telephone Company v. Graff-Baker.

The hearing of this action was resumed yesterday in Chancery Court IV., before Mr. Justice Kekewich. Mr. Swinburne was cross-examined, and M. Abdank-Abakanowicz gave evidence as to the superiority of metallic circuits for telephones, and also as to the Budapest and Vevey systems of traction, showing that the latter had, to some extent, disturbed telephones in the district. Mr. Stephen Sellon also gave evidence as to the Budapest line. Mr. R. Winthrop Blackwell said that he had constructed numerous electric lines in the United States, both with metallic returns and upon the single wire system, and stated that in his opinion the only practicable system of electric traction for streets was the single wire overhead system. Mr. Clarance Leighton said that he had seen an exchange in Stockholm with some 9,000 subscribers, of whom between 2,000 and 3,000 had metallic circuits, the remainder having earth returns. A full report of the proceedings will appear in our next issue.

* Abstract from an article by P. Clémenceau in *L'Electricien*.

CORRESPONDENCE.

OIL TRANSFORMER EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your issue of December 9, 1892, under the heading "Notes," some results obtained by Mr. Campbell Swinton with an oil-immersed induction coil working with condensers in substantially the same way devised by me for getting high-potential discharge. I refer to the experiments in which an incandescent lamp is lighted by the discharge of current passing, and which can be but a small fraction of an ampere.

I desire to say that similar phenomena were noticed by me in my early working with the apparatus. In fact, I found that on putting an incandescent lamp in the path of the discharge, not only was the filament brought to very high incandescence inside the bulb, and before the bulb broke, but that the filament itself was thrown from its supports, thrown around in the bulb, and the bits of filament moving about in the bulb were brought to brilliant incandescence. This was generally followed very quickly by the breaking of the bulb and the complete destruction of the lamp. Knowing that the current flowing was insufficient to bring about such a high incandescence of the filament, unless some new action came into play, I took an ordinary filament, without any enclosing globe, and placed it in the line of the discharge. I found that in this case the spark entering at one end of the filament and passing out at the other produced the same brilliant incandescence of the filament traversed by the spark. These filaments would have required more than an ampere to have brought them to equal incandescence by the ordinary lighting currents. I came to the conclusion, which I am pleased to note has been suggested by Mr. Swinton, that the filament did not actually conduct the current through its mass, but only upon the surface, and that, therefore, it became practically of very high resistance, so that a very small current would bring it to incandescence. These experiments were carried on over six months ago, since which time I have constructed a much larger coil, on the same general line as my first apparatus, but which is capable of giving discharges between its rounded terminals 64in. apart, and this limit of striking distance was evidently not the limit of the apparatus, because the terminals could not be further separated. There was no difficulty in getting the 64in. discharge as often as might be desired, or it might be continued as long as desired. The sparks took the form of a torrent, resembling in the most striking way lightning flashes, and they were accompanied by enormous developments of ramifying sparks in all directions from the electrodes. The development of ozone in the neighbourhood of the apparatus during the passage of the discharge is so great as actually to be very disagreeable and irritating. I think it quite possible that apparatus of this kind may be found useful in the artificial production of ozone. It is not, however, likely that such extreme potentials will be needed, but, by changing the gauge and length of the secondary coil immersed in oil, the potential, as well as the current which may be evolved, can be controlled.

Our experience shows that these high frequency discharges are not by any means harmless, as it was found that a kitten placed in the path of the discharge was instantly killed. While, no doubt, for some reason or other, an increase of frequency may lessen the danger to life, as shown by the experiments of Dr. Tatum, there is no certainty but that at

Hosted by Google

some still higher frequency increased danger may exist, and for the present at least we must come to the conclusion that wherever high frequency currents have apparently been harmless there has simply not been enough current to do any harm.—Yours, &c., ELIHU THOMSON.

Lynn, Mass., December 28, 1892.

THE PERIODS OF ELECTRIC RESONATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There is a point in connection with the experiments of MM. Sarasin and De la Rive on electric radiation,* which may, perhaps, merit some elucidation. How is it that the wave-length in ether corresponding to the free period of a circular Hertzian resonator comes to be so much as "very approximately" eight times the diameter of the resonator?

The frequency of the vibrations in question appears to be so great that the degree of conductivity of the material of the resonator does not affect them. Under these circumstances it is simply a matter of the vibration of the free ether without any sensible dissipation of energy, and the mode of the vibration may be represented by imagining the ether to be an incompressible elastic solid medium, with cavities in it in the places of the conductors (which we may for convenience imagine to be filled with incompressible fluid devoid of inertia), and the walls of the cavities having so great stiffness that any point on one of them may move at right angles to the wall, but not tangential to it.† Now, the wave-length of the free vibrations of a system like this should be somewhat less than twice its greatest linear dimensions, for the same kind of reason as applies in the analogous case of the free periods of a sounding pipe or other partly enclosed air-cavity. We should expect the wave-length to be less than twice the diameter of the resonator.

The explanation is, perhaps, to be sought for in the static capacity of the condenser formed by the two balls which terminate the wire of the resonator. The system is, in fact, tuned by adjusting these balls. In the extreme case when they are replaced by two parallel plates, very near together, and therefore of considerable capacity, the electric oscillations become comparatively slow; so that Lord Kelvin's formula for the period, $2\pi\sqrt{CL}$, where C is the capacity of the condenser, and L is the (constant) self-induction of the system for steady currents, holds good, and shows at once the effect of capacity. This is, in fact, very easily followed in the mechanical illustration quoted above, in which the easy mobility of the plate representing the dielectric of the condenser slows the period.

A similar cause would also increase the free wave-length of the Hertzian resonator, but not to an extent readily amenable to calculation. Only the observation that the wave-lengths of different circular resonators are proportional to their diameters would seem to require that these resonators, the terminals included, are all geometrically similar to one another.—Yours, &c., J. LARMOR.

St. John's College, Cambridge, Jan. 9, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is now at press, and will shortly be ready. Firms and others who have not returned the slips asking for information are requested to do so *immediately*. The price of the Directory and Handbook will be as before: *Subscription*, 5s.; after publication, 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

* *Comptes Rendus*, December 26, 1892; *The Electrician*, January 6, 1893.

† See *Proc. Camb. Phil. Soc.*, Vol. VII., 1891.

TENDERS INVITED.—In our advertisement pages tenders are invited for an installation of wiring and fittings for the electric light (about 80 lamps) in a private house in the suburbs of London. Tenders should be delivered to M. J. Dary, 19, Dashwood House, Old Broad-street, E.C., not later than Saturday, January 21st.

——— Our readers will remember that the date for sending in tenders for the supply and fixing of fittings for the electric lighting of the interior of the Town Hall, Burnley, is Wednesday, January 18th.

SALE BY AUCTION.—Messrs. Wheatley, Kirk, Price, and Goulty will sell by auction on Wednesday, January 25th, and following days, a large quantity of machinery and appliances, engines, boilers, shafting, hydraulic presses, pumps, fittings, and fixtures, on the premises of the Swaisland Printing Offices, at Crayford, Kent. The sale commences each day at 10 for 11 o'clock prompt.

APPOINTMENT VACANT.—The county borough of Halifax require an electrical engineer, at a salary of £200 per annum, capable of advising the Corporation on the lighting of the borough. Further particulars are given in our advertisement columns, and applications must be in by Thursday, January 26th.

ECLIPSE ELECTRIC LIGHTING SYNDICATE (LIMITED).—Claims against this Syndicate, in voluntary liquidation, must be sent in to Mr. E. R. Wood, 8, Finsbury-circus, E.C., by February 14th.

DISSOLUTIONS OF PARTNERSHIP.—Easton and Waldegrave, electrical and mechanical engineers, Whitehall Foundry, Taunton; debts by W. W. Easton.——Hill and Co., electrical and scientific apparatus makers, 2, Aldersgate-buildings, E.C.; debts by A. L. Adams.

POOLE AND WHITE (LIMITED).—The following is the list of principal creditors in this failure:—

The determinations arrived at by the recent meetings of the creditors and the contributories will be considered before Mr. Registrar Emden, at Bankruptcy-buildings, Carey-street, on Jan. 18th, at 11.

ELECTRO-MEDICAL APPARATUS COMPANY.—In the note referring to this Company last week, a clerical error made "from 1 to 100 milli-amperes" into "1 to 1,000,000 amperes."

MESSRS. DRAKE AND GORHAM.—This firm, during the past year, have received contracts for no less than 96 installations of the electric light, equal to considerably over 10,000 lamps. A number of these installations were at country houses throughout the country, where petroleum engines of Messrs. Priestman's and Messrs. Crossley's make have been in several cases used. In conjunction with Captain Holden, Messrs. Drake and Gorham have introduced some new recording instruments, and these have been very favourably received, more particularly those of the photographic type; their electrostatic indicator has been further improved, and a steady demand for the instrument is the result. The D. P. battery has also undergone improvement during the

Hosted by Google

year, and satisfactory progress is recorded in the sale of these batteries. As was to be expected, there has been a large sale of the Cardew instruments, the patents for which are held by Messrs. Drake and Gorham. The firm have in past years made a feature of electric hoists, and they are now installing a passenger and luggage hoist at Callaby Castle, Northumberland, in connection with the electric lighting installation. This lift has all the latest improvements, and is to be driven by a 6 H.P. motor.

THE SILVERTOWN COMPANY.—During the past year, in addition to the usual rubber and gutta-percha manufactures, the Company's electrical department has made and laid a submarine cable of more than 2,100 knots in length, connecting Senegal in Africa with Pernambuco in Brazil. Another cable to duplicate the system originally laid down by this Company for the Central and South American Company has also been manufactured during the past 12 months, and is now on board the "Silvertown." This cable is of a total length of 2,620 knots, and will be laid from Salina Cruz Mexico) to Chorrilas (Peru), touching at Sta. Elena (Equador) and San Juan del Sur (Nicaragua). In addition to these the Company have manufactured a large amount of cable for the telegraph companies and the British and Foreign Governments, representing a total of 5,400 knots for the year. The Company have also been busy with electric light cables, which have been supplied, and in some cases laid, for Dublin, Leeds, Oxford, Cambridge, Dundee, and Glasgow. The demand for cables and wires for installation work has been very heavy, and the Silvertown Company have secured nearly all the Admiralty orders for *main* cables. The Company's machinery department has been fairly active, and the orders have included sets of dynamos for the British Government and for the extension of the Hague Tramways Company. The outdoor department of the Company's business has been busy with installation work for shops, factories, and private houses, and the instrument and battery shops have been fairly well employed on Government and other work.

MESSRS. TOWNSEND AND MACINTYRE.—The address of this firm is 15, Brook-street, London, W.

BREWERS AND ALLIED TRADES' EXHIBITION.—The success of the Brewers' Exhibition in London (at which several electrical firms exhibited) has led to the promotion of a similar show at Birmingham This is to be held in the Bingley Hall from April 13th to 22nd next. Mr. G. Emett is general manager, and the offices are situated at 66, Finsbury-pavement, London, E.C.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—An interesting pamphlet is issued by this Company dealing generally with the question of Municipal Electric Lighting. The object of the Company in issuing this pamphlet has been to treat the subject from a popular rather than from a technical point of view, and especially in the hope that members of Municipal Councils of the country will find information therein of service when discussing the subject of the introduction of the electric light into the districts which their local authorities serve. The pamphlet includes: "Definitions of Electrical Terms," "Parliamentary Regulations Regarding Municipal Electric Lighting," "Systems of Generation and Supply," different forms of "Motive Power," a short chapter on "Street Lighting," and "Cost to the Consumer."

ELECTRIC CONSTRUCTION CORPORATION.—A handsome catalogue, with price list of the electrical machinery and apparatus manufactured by this Corporation, has been recently issued. The general contents are preceded by large illustrations of the Manchester-square station of the Metropolitan Electric Supply Company, and of the central station of the Liverpool Electric Supply Company, an electric travelling crane, conduit tram car, and a switchboard. Illustrations of various patterns of Elwell-Parker dynamos and motors for continuous and for alternating current are given, together with a very complete price list. The list, which includes transformers, switches, cut-outs, &c., is excellently printed and substantially bound.

MANCHESTER EDISON SWAN COMPANY (LIMITED).—For the past year this Company report an unusually busy time, not only in their manufacturing department, where they have considerably increased the output, but also in connection with their installation department, which has carried out a large number of installations in Manchester, Sheffield, Leicester, Gloucester, Rochdale, and other towns in all parts of the country. These installations include clubs, banks and insurance offices, hotels and restaurants, several of the leading newspaper offices, two theatres, and a long list of business premises. The result of this large access of work is that their present factory has become too small, and the Company have under consideration the building of large new works outside Manchester. New showrooms are being prepared at the Exchange Approach Station, Manchester, where complete sets of electric lighting plant will be in operation. The Company are applying for a Provisional Order covering the districts of Altrincham and Bowdon, under which it is proposed to lay down a central station with a capacity of 15,000 8-c.p. lamps.

MESSRS. MATHER AND PLATT.—The London branch of this firm are carrying out an electrical installation at the East London Water Works, Lea Bridge, the total number of lights being about 250. The firm have also in hand an order for the fitting up of the Manchester New College, Oxford, including the library and chapel; and also the electric lighting installation for the *Lancet* printing and publishing offices, Strand, W.C.

CALENDARS, 1893.—Messrs. Shand, Mason, and Co. are issuing a hanging calendar, with date pad attached, the frontispiece of which is a drawing by Linley Sambourne.

ANNUAL DINNER.—The annual dinner to the *employés* of the Exchange Telegraph Company was given on Saturday last at the London Tavern, Fenchurch-street, and proved a great success.

BECKENHAM.—Mr. Kapp's report respecting the cost of the necessary works to provide electric current for the compulsory area included in the Provisional Order, has been submitted to the Local Board.

BOMBAY.—An electrical power transmission plant has recently been erected at the Mannockjee Petit Mills, Tardeo, Bombay. The work has been carried out to the designs of Messrs. Nowrosjee Wadia and Sons. We understand that the machinery has worked very satisfactorily.

BUDAPEST.—Messrs. Ganz and Co., of Budapest, have definitely received the contract for the central station at Sophia, Bulgaria. Water power is to be utilised, and some difficulty is anticipated in connection with it owing to its high-pressure. The Mannesmann Tube Company have the contract for the supply of seamless steel pipes to conduct the water to the turbines, and have given a guarantee for their efficiency.

CARDIFF.—In reference to the arrangements being made to prepare a scheme for the electric lighting of Cardiff, it is suggested that water power be utilised from the mains from Cantreff to Cardiff.

CHRISTMAS TREE LIGHTING.—On Tuesday last a children's treat was given to the school children of the Ward of Farringdon Without, London, E.C., at which a huge christmas-tree formed an interesting feature. The Edison and Swan Company supplied a large number of electric glow lamps, and Messrs. Lund Brothers supplied the necessary current and undertook the work incidental to the lighting of the tree by electricity.

CORINTH.—The cutting of the canal across the Isthmus of Corinth is approaching completion, and it is anticipated that it will be possible for a large steamer to go through at the end of April next. The canal will be lighted by electricity; two powerful lights having been placed at each end, and a row of lamps throughout its entire length.

DOVER.—The Mayor, Aldermen and Burgesses of the Borough of Dover announce that they propose to transfer their powers under the Dover Electric Lighting Order, to a company to be called the Dover Electric Supply Company (Limited). The area of supply is the whole of the borough, and the Company may be required to sell to the Corporation at the period of 21 years, and subsequent periods of 10 years.

EDINBURGH.—As a result of the recent visit of a deputation of the Edinburgh Town Council to the various electric lighting stations in London and the provinces a report is to be submitted to the Council in a few days. A feature of the report will be the particulars it will contain of the effect the introduction of the electric light has had upon the consumption of gas in the districts visited. For instance, from Newcastle it is reported that the introduction of the electric light has led to an excess consumption of gas, owing to a desire on the part of gas users to display their wares with increased effect. The deputation have expressed themselves equally favourable to both the high and the low systems of supply.

EDISON-SWAN COMPANY (LIMITED).—The annual entertainment given by this Company to its *employés* at Ponder's End was recently held. Owing to the large number of workpeople employed, it is necessary to have two entertainments. It will be remembered that the Company recently applied for and obtained a licence for music and dancing for their *employés'* entertainment hall. A feature of the affair was a presentation to upwards of 300 of the best timekeepers in the Company's employ, the presentation being made by Mr. Gimingham, the manager of the works.

EDMONTON.—The Board of Guardians at their last meeting discussed the advisability of introducing the electric light to the schools and other premises under the control of the Board, and it

Hosted by Google

was decided that the time had arrived for giving the matter consideration.

FROME.—The Local Board is in treaty with the Gas Company for the taking over of the gas works, and are disposed, should the terms be unfavourable, to invite tenders for the lighting of the town by electricity. The matter has been referred to a committee.

GLASGOW.—The Electric Lighting Committee anticipate that the lighting of the Glasgow streets by electricity will not be completed until about March.

HECKMONDWIKE.—Further discussion on the subject of preparing a scheme for the introduction of the electric light into Heckmondwike has been deferred to the next meeting of the Board.

HULL.—The Electric Lighting Works at the Hull Docks are now complete. The inauguration ceremony will take place at the Town Hall on Monday, when, for the second time, the Corporation buildings will be lighted by electricity. It will be remembered that the first attempt to introduce the electric light into Hull was a failure. At this, the second attempt, everything has been done to render the installation a success. It is contemplated that the principal streets of the town will shortly also be lighted by the electric light. After the inaugural ceremony, an Electrical Exhibition is to be opened, and a lecture delivered on electric cooking and heating, by Mr. H. J. Dowsing.

LIVERPOOL.—The Council Chamber at the Town Hall is now lit by the electric light, and it is generally agreed that the illumination is much more satisfactory than hitherto.

PORTRUSH.—The Town Commissioners' contract with the Gas Company expires on the 1st prox., and at a recent meeting Captain Massey proposed that the Commissioners should obtain a loan of £5,000 to acquire the old mill at Glenmanus with its water-power, and also the water-power of the Glenmanus Burn, which, as he believed, would be sufficient to supply motive power for an electric lighting installation capable of lighting the whole of the district. He complained of the insufficiency of the gas supplied and its cost. A committee was appointed to make inquiries as to the best means of lighting the town by electricity, and to report to the Board at the earliest opportunity. The committee were empowered to obtain the assistance of an engineer if necessary.

PRESTON.—At the annual gathering of the *employés* of the Preston Electric Supply Company (Limited) a satisfactory report was given by the manager of the Company on the past year's work. He was able to state that the growth of business was represented by 6,000 lights for 1892, as against 2,000 for 1891. The Company had supplied a large number of electric motors, which, he was pleased to say, had been found to compare as to cost favourably with other motors. The Company had proved a success.

READING.—At the last meeting of the Town Council the report of the Electric Lighting Committee, recommending the acceptance of the terms offered by the Reading Electric Supply Company (Limited), was adopted unanimously. The negotiations between the Electric Lighting Committee and the representatives of the Company have been lengthy, and seemed a short time back to be likely to result in failure. By the terms now agreed upon the Council have arranged that the Company shall work the Provisional Order, and if the Council shall ultimately decide to purchase the undertaking it will be on the basis of £133 for every £100 expended by the Company, subject to the amount expended being certified by the Board of Trade auditor year by year. As an earnest that work is shortly to be started, the tenants on certain land belonging to the Council, which is likely to be required for the central station, have received notice to quit.

RUNCORN.—At the meeting of the Improvement Commissioners last week a motion was carried to instruct the Canal Boats and General Purposes Committee to inquire as to the probable cost and practicability of installing the electric light for the public lighting of Runcorn, and to report to the Board at the earliest opportunity.

SINGAPORE.—Mr. O. V. Thomas, electrical engineer of Singapore, has recently sent in a tender for the installation of arc lamps for the public lighting of Singapore of a temporary character, the Thomson-Houston system being adopted. The estimate of Mr. Ritchie, the municipal engineer, for lighting the whole town, is $350,000.

STAGE EFFECT AT THE NEW OLYMPIC THEATRE.—In the course of Mr. Oscar Barrett's present production of *Dick Whittington*, the stage gradually darkens, and a screen, placed in the background, is illuminated with a number of tiny incandescent electric lamps, which appear to twinkle like stars, representing the cluster of stars in the constellation of Hercules. To produce the effect 400 incandescent lamps, run on twenty distinct circuits, are employed. All the circuits are joined to two copper conductors placed at the top of the screen, and each circuit is protected by an automatic cut-out. For the desired variation in the brilliancy of these artificial stars, lamps of voltages varying from $3\frac{1}{2}$ to $4\frac{1}{2}$ volts are used. The batteries are placed on the stage, and are of the Lithanode type. The screen was designed and manufactured for Mr. Barrett by the Lithanode and General Electric Company, of Westminster.

SUNDERLAND.—The Town Clerk has been instructed to write to certain firms asking upon what terms they are prepared to undertake the work which the Corporation require in connection with the proposed adoption of the electric light for the borough.

TUNBRIDGE WELLS.—It has been decided to print the report of the Electric Lighting Committee dealing with the cost of the electric light scheme which is before the Town Council. In order to meet the expenses necessary for the building, &c., in connection with the lighting order, it has been resolved to charge the maximum price per unit allowed by the Board of Trade until circumstances justify a reduction. Mr. Preece, who has advised the council in the matter, has been requested to prepare the plans and specifications for the necessary buildings.

WHITEHAVEN.—The large engineering works of Messrs. Ramsey Brothers, in Albion-street, Whitehaven, have recently been lighted throughout by the electric light. Brockie-Pell arc lamps are used in the installation, as well as a large number of incandescents. The work has been done by Mr. Watson Bell, of Whitehaven. The *Workington News* of the 7th inst. devotes two columns of small type to a description of the installation.

COMPANIES' MEETINGS & REPORTS.

International Okonite Company (Limited).

The adjourned annual meeting of the shareholders of this Company was held on Tuesday at the Cannon Street Hotel, Mr. Samuel Pope, Q.C., presiding.

The CHAIRMAN stated that, unfortunately, he was absolutely unable to be present at the former meeting, which was convened for November 30th, and which was adjourned until that day. The present was, therefore, so to speak, a continuation of the former meeting, and, with their permission, they would resume the discussion on the report and balance-sheet at the point where it left off before the adjournment. He owed them a word of thanks, because he could not help believing that the cordiality with which they received the suggestion for adjournment arose partly from considerations for himself, who was unable to be present. He would be glad now if any shareholders would ask for any information regarding any point, and, as far as he (the Chairman) was concerned, any explanation which was desired should be offered as far as the question was capable of explanation. A few questions were raised at the last meeting upon which he would like to say a few words. The first point that appeared to him necessary to refer to in the balance-sheet was the £20,000 which practically had been refunded out of the purchase-money by the original vendors, who were the managers in America. This matter had caused the Directors very great anxiety, and there had been considerable negotiations regarding it at the beginning of the year. They found in the course of their business that the valuation of the stock upon which their previous profits had been nominally based was practically an over-sanguine valuation. They therefore, of course, felt bound, as Directors, not to proceed to present any balance-sheet in which the assets were, in their judgment, over-valued, and therefore, of necessity, the present balance-sheet had to be prepared upon an amended valuation of the stock consistent with what they believed to be its true and legitimate value. Of course, the profits of the present year would be necessarily diminished by the amount which they thought it necessary to write off the original valuation, for the profits depended very largely upon a true valuation of the stock. Therefore they felt that, inasmuch as their previous balance-sheet had been very largely based upon the valuation for which their American colleagues were responsible, and largely also upon the valuation for which the original vendors were responsible, it was advisable to send their general manager to America with a view to insisting upon some return to the Company of the purchase-money which had been paid on the basis of such valuation. After considerable difficulty they induced those gentlemen to hand over, for the purpose of cancellation, £20,000 of the shares which had been given to them in part payment of the purchase price, and this £20,000 had been treated as a reduction of capital, because, of course, the shares which were issued and upon which dividends—if any should be earned – would be payable would be diminished by this £20,000. This seemed to him to be fairly and correctly stated in the report, and he owned that he did not see how the Directors could either have done other than they had done, or treated the amount which had been so refunded in a different way, because it was practically £20,000 repaid out of the purchase-money by reason of their insisting that the valuation should be rectified, and he would never have been a party to presenting a balance-sheet if it were

Hosted by Google

to show a profit by an over-valuation of stock, although that might have been the principle upon which it had been valued before. Therefore, one of the main features of the present balance-sheet was that they hoped and believed that they had started with a proper valuation of their stock at Passaic,—a real, true, sound valuation—and although, the writing off of £20,000 from the valuation of the stock prevented any profits from accruing this year, the advantage of it would be derived hereafter, because in the future there would be no such over-valuation to contend against. Something was said at the last meeting, by way of inquiry, regarding the London expenses, amounting to some £2,000 odd. These were the entire expenses of the Company in England, because, wisely or unwisely, their Company, although largely consisting of property in America, was managed by a board in London. The expenses in question consisted of rent, rates, taxes, stationery, printing, postages, wages to secretary and accountants, and various other incidental expenses, which were, of course, inevitable. However, out of the £2,000 odd, £750 was repaid to them by other companies who had the advantage of using this Company's staff and establishment, so that the net expenses would be the amount appearing in the balance-sheet with the allowance of this £750. The Manchester business showed a considerable loss. The Directors were unanimous in their opinion that it ought not to do so, and they were equally unanimous in their opinion that the management of the Manchester business had been not only disastrous, but disgraceful. They had, therefore, thought it right to remove from the service of the Company the gentlemen who had hitherto been in charge of the business in that city. They were unanimous in believing that they would be able to reorganise the Manchester factory upon a basis which would make it satisfactory and profitable, but the agreement which, in the first instance, was made with the vendors of the Manchester business had operated to hamper the discretion of the Directors. They were unanimous, however, in their opinion that, at any cost, if cost were necessary, a "clean sweep" must be made in the management of their affairs in Manchester, but this could not be done in a moment, or without a certain amount of difficulty. He knew that there might be some differences of opinion on this point, and shareholders were entitled to hold other views. He desired, however, to say frankly that the Directors were unanimous on this matter, and if there were a feeling upon the part of the shareholders that the Manchester business should be left in the hands of those with whom the original agreement left it, the Board asked to be relieved from any responsibility in the management of the concern. If it was the view of the shareholders that the Manchester business should be left with Mr. Conolly—and he would even say with Mr. Shaw—the Directors would not consent to hold office under any such conditions.

Mr. CONOLLY: That is special pleading.

The CHAIRMAN: I do not know what you mean by special pleading; I think it is a direct statement enough. We think that you have so mismanaged the Manchester business that we are justified in discharging you. Continuing, the Chairman said that the shareholders might judge of the propriety of the Directors' decision by what had just taken place. He (the Chairman) thought that the Manager was subservient to the Board. As long as he held his present position that would be so, but the simple circumstance which had just arisen illustrated the difficulties which the Directors had had from the first in carrying out what they believed to be their duty. Some of the views and criticisms which had been expressed by the gentlemen who had issued a circular to the shareholders were in his judgment, though he did not say this was the deliberate opinion of the Board, well worthy of respectful consideration; but the first thing to be done was to secure management which they thought would be competent. The gentlemen who had issued the circular in question had deposited with the Company a certain number of proxies since their last meeting with a view, probably, to use them in the enforcement of their opinions. These proxies covered 1,803 shares distributed among 79 shareholders. Some had been sent too late in any case for use, representing about 60 shares more, so that the support which had been accorded to the circular amounted, at the outside, to 1,863 shares. If he were called upon as Chairman to rule as to the legality of these proxies he should say that they could not be used, because the present was part of the general meeting, and no proxy which was not delivered by a certain time before the meeting, of which the present was simply a continuation, could be legally exercised. He did not, however, think it was necessary that he should absolutely rule to that extent. The Directors held proxies for 11,221 shares. There could not be any objection to a full ventilation of opinion at the meeting; but if the Directors were put to it, or if he were asked to rule, he should rule against the use of the proxies on the other side to which he had alluded. The Directors had an overwhelming majority of the confidence of the shareholders, and it could, therefore, hardly be worth while to put them to the trouble of a vote in such a case as the present.

A SHAREHOLDER: But there may be a question as to the validity of the Directors' proxies.

The CHAIRMAN said he would be prepared to rule upon this question when it was raised. He then quoted from the circular in question, and in answer to one of the statements therein said that the Directors did their best to settle the difficulty which had arisen in America to which he had already alluded. He thought that there should have been more restitution than the £20,000 mentioned, but they had done the best they could and had got all that they could. The circular went on: "Apparently, on the face of it, the report would convey the impression that the difficulties with regard to management are of very recent date, whereas we have reason to believe that such is not the case." The difficulties occurred during the year covered by the report—the American difficulties in the earlier portion of the year, but the Manchester difficulties came to their knowledge afterwards. He might say that, for a long time, he was in hopes that the Manchester management would justify itself, and that they would have a business there which could be conducted profitably, and the disappointment had been a very bitter one to him. They came to the conclusion late in the year that it was impossible to continue the Manchester business under the management which then existed. The circular continued:—"The state of the Company's business as disclosed in the balance-sheet calls for at least a Committee of Inquiry fully empowered to ascertain all details of the Company's business, and that such Committee should present a report of their investigations to the shareholders." If the shareholders desired such a Committee they must get rid of the present Directorate. They would regard it as a vote of want of confidence in the Board, and they would not allow any such Committee to interfere with their administration—at all events, under existing circumstances, which were difficult enough to deal with. Then, the circular said, "If no Committee be appointed, most certainly a change ought to be made in the Directorate of the Company, and, if possible, Directors appointed who would be able to devote attention to the Company's affairs, and to influence business and the introduction of business." He did not know what that meant. The circular continued: "The balance-sheet of the Company, as presented with the report is of a very meagre character, and does not give sufficient data to enable the shareholders to ascertain fully the losses and where the losses have arisen." Well, he never knew a balance-sheet which gave such particulars in detail. The circular added: "Generally speaking, we are of opinion that in the interests of the shareholders themselves, they should demand the fullest explanation of these matters." Well, generally speaking, he was of opinion that in the interests of the shareholders the fullest explanation on all matters should be asked for and should be furnished. The circular was signed by Mr. John Kenyon, who held 100 shares; Mr. Henry Lacy Peters, who held 50 shares, Mr. Thomas Thorp, who held 250 shares, Mr. Edward Gladstone, who held 10 shares, and Mr. William Griffiths, who held 30 shares. Out of the total capital of the Company 2,420 shares were represented in the opinions expressed in the circular. He moved the adoption of the report and balance sheet.

Mr. GLADSTONE asked who were the vendors to this Company.

The CHAIRMAN: The American Okonite Company.

Mr. GLADSTONE said he thought it was the Woodhouse and Rawson Company.

The CHAIRMAN replied that the Woodhouse and Rawson Company sold to this Company the agreement which they had made with the American Okonite Company.

Mr. GLADSTONE quoted from the prospectus, and said that what he wanted to get at was, who were the vendors?

The CHAIRMAN: They are stated in the prospectus.

Mr. GLADSTONE: Are you one of the vendors?

The CHAIRMAN: No, I am not.

Mr. GLADSTONE said it appeared to him by the prospectus that the Woodhouse and Rawson Company were clearly the vendors to the Company.

The CHAIRMAN, in answer to Mr. Holt, said that they believed that the £111,000 in the balance-sheet standing against stock-in-trade represented the actual value of that item. There had been no "ruinous loss" at Manchester.

A long discussion followed, in which Messrs. Holt, Gregory, Hawkins, Emery, Mather, William Griffiths, Hopps, and Bond took part, the nature of the remarks and criticisms being indicated by the subsequent replies of the Chairman and of the Managing Director (Mr. Vaughan-Stevens).

Mr. F. L. RAWSON (Woodhouse and Rawson United) said that the business, in his opinion, was a first-class one, and he had shown his belief in the Company by the amount he had invested in it, for probably at the present time he was, outside the vendors, as large a holder as any two gentlemen in the Company. He originally held £10,000 in ordinary shares, and his holding now in ordinary shares and debentures represented very nearly that amount. The business in America itself had been most profitable, but in the year after the Company was formed they had a very bad time there—the worst they had ever had. When he went to America to verify the statements made by the vendors he chose the firm of Messrs. Price, Waterhouse, and Co. to assist him, regarding that house as the most competent to test the statements in question. One of the partners of that firm accompanied him to America. When they came to test the stocks, &c., they only had a certain time in which to do it. The vendors had already raised their price on the ground that their business was progressing so much, and the option of purchasing it was only given to them up to a certain time. They discussed the matter most fully, and eventually he absolutely refused to do anything further unless the vendors showed their good faith in regard to their statements by depositing the shares they were to receive, as security. To this they assented, and he did not suppose that they would have been able to recover anything from them had it not been for the fact that the shares had been so deposited. With reference to the loss that had been made, it was but a small one for this class of business. He knew of one firm in it which, not long ago, lost more than their capital, and yet within two years recovered it all and held £30,000 in the bank besides. It was not true that Woodhouse and Rawson United were responsible. Where he expected to make large profits was in America; but unless they strengthened the Directors' hands, what had occurred before in other cases would happen to them, and they would lose their money, owing to differences among themselves. The whole point for their consideration was whether, by dissensions among themselves, they should allow other people to derive the full benefit of the business.

Mr. GLADSTONE inquired if any application had been made to the Woodhouse and Rawson Company to return any of the money they had received as vendors.

The CHAIRMAN replied in the negative, but added that such an application would have been made had the Woodhouse and Rawson Company done anything except sell to this Company the agreement they had made with the American Company. They had discharged their liability to the Company.

Hosted by Google

Mr. GLADSTONE: Well, that is a matter of opinion.

The CHAIRMAN: Not at all, it is a matter of fact.

Mr. KENYON asked whether it was not the fact that up to the time of the Company taking over the Manchester business the business of Messrs. Conolly and Shaw had been very remunerative.

The CHAIRMAN said that it had been thought so.

Mr. KENYON asked whether the Directors had themselves obtained a single order for the Company.

The CHAIRMAN: It is not the duty of Directors to "tout" for orders. He added, in answer to Mr. SQUIRE, that practically no Okonite had been manufactured at Manchester.

Mr. SQUIRE said he thought that there must be "something rotten in the State of Denmark." If he had a manager who did not obey his instructions he would get rid of him.

The CHAIRMAN: That is precisely what we have done.

Mr. SQUIRE urged the shareholders to trust the Board.

The MANAGING DIRECTOR (Mr. Alfred Vaughan-Stevens), in reply, said that the original prospectus stated that the agreements as to the purchase of the various properties might be seen at the offices of the Company. He had charge of those agreements at the time, and he could assure them that not a single shareholder applied to see them. They embodied the whole of the information about which it was very necessary that the shareholders should be informed, in the event of their wanting to plead later on that it was through sheer ignorance that they took their shares. It was very evident that those who had asked what profit the promoters made out of the business had not seen the agreements. Woodhouse and Rawson made, on paper, £46,500, but, as a matter of fact, that Company had not made a penny, because the whole, and more than the whole, of that supposititious profit was represented by shares or debentures which they took in the Company, and therefore they stood to sink or swim just as much, or more so, than any shareholder in the room. The Chairman had answered a question on his behalf, and had stated that when he joined the Company he was not a technical man. Perhaps it would have been better to have obtained a technical man, but his knowledge at that time and now were two very different things. Unfortunately, the experience he had gained had been a very hard one. In November, 1891, after the first annual meeting, he went to America, as a police officer would say, "from information received," and the information he received was very startling. One result of his visit was an alteration in the management in America, and also an alteration in the Board of directors resident in the United States. He was not going to explain the entire reasons which led to his going to America, and which led—after three weeks' protracted discussion between three or four of the most eminent legal firms in New York, and after repeated telegrams to the Directors in England — to the fact that, after having claimed £50,000 or £60,000 in cash, he received only £20,000 in shares. He would merely state that he got all he could, and he could assure them that it was utterly impossible to obtain anything further. He by no means said that the £20,000 in shares represented what the Company ought to have recovered; and he asserted that if he had got all that he had been really entitled to, the profits of the Company, notwithstanding the heavy losses in Manchester, would have been most satisfactory. A question had been asked as to the working capital. It was put down at £110,000, but originally £15,000 of debentures were not issued, which reduced the amount to £95,000. The sum to be remitted to America as working capital was £65,000, so £45,000 was supposed to have been left for this side, but, as he had said, £15,000 of debentures were unissued, so that the amount was reduced to £30,000. Unfortunately, owing to the advice of the experts of the Company, headed by Mr. Thomas Conolly, they spent the money almost before they knew where they were, and he had that day sufficient experience to know that a good deal of the money had been very foolishly expended, and that results from the outlay would not come back for some time. He thought that if they had spent their money properly they would have received a return fully in accordance with the statements made in the prospectus, for which, however, he was in no way responsible, nor were any of the Directors, he believed. With respect to the management of the Manchester business, they were at present in a state of interregnum. They had discharged the people who formerly conducted the business there. Those people sold the Company their trade secrets, their secret processes, and their goodwill, but, as a matter of fact, they refused to part with all three. The Company had a very difficult task indeed before them to find another works manager who would know the whole of the business which the Company required to know. There were only two, or perhaps, at the outside, three successful cable manufacturing companies in England, and their success was almost entirely owing to the efficiency of their works managers. The only possible way for their Company to act was to train up a man, and they intended to do so with the least possible delay. Their late works manager had grossly mismanaged their factory, but beyond that he did not wish to say anything in explanation of the present state of affairs. The Articles of Association provided for the payment of a sum of £1,500 for the Directors in England, and he certainly thought that those gentlemen had earned it. Had the Company been successful, the Directors would not have half the trouble which they had had. The Chairman's time was extremely valuable, but he had given ungrudgingly every possible assistance to the Company's affairs, and in a way that they were not entitled to expect. His (the speaker's) remuneration was £1,000 a year, and if he had known the trouble which was going to be given to him for this sum he would not have taken the office. As a matter of fact, however, he was not receiving anything in cash, but was being paid in debentures.

Mr. KENYON: Well, the ship is sinking.

The MANAGING DIRECTOR: It is not sinking unless you sink it, Mr. Kenyon. You have damaged our business greatly, and you, who wanted to become a Director of this Company, are mainly responsible for any difficulties that may occur. You have done this Company an amount of harm by damaging its credit which you can never repair. Continuing, in reply to other questions, he said that the trustees had been paid £200 a year, but they wished to retire, and did so. The Chairman thereupon offered to take the office as one of the trustees without remuneration, and he (the speaker) offered to do the same. The Company thus saved £200 a year. Mr. Kenyon had handed him a note, in the handwriting of Mr. Robert Shaw, a discharged Clerk of the Company: "Have any losses been charged to this Company on any rubber transactions between the Managing Director and the manager in New York?" In so many words, that imputed fraud, and he declined to answer such a question. Mr. Squire had asked the reason why they had not made okonite in England. He only regretted that he was led by the works manager, and had not put his foot down and said, "You shall not make any more of the stuff you have been making." Unfortunately, they had run away from the manufacture of okonite, but they would come back to it. With respect to the management in America, the business, after dropping off through bad management, had been put into really good hands, and the last report he received, giving detailed accounts month by month, showed that their business in America was steadily increasing. As a proof of the satisfactory position of the business in that country, he might state that the managers there were pressing him not to make any more experiments in this country, and to shut up the English business if they could not make it succeed now. They might find it necessary to lose a little more money in reorganising the business here, but they would not lose much. He might state that the largest sales ever made by them in America in any one month amounted to $100,000, whereas their sales last October amounted to $85,700, and they were very nearly as large in the preceding month. The depreciation was only shown on machinery, tools, &c., and he did not believe that they could write depreciation off goodwill. It was also foolish, if the sales could be kept up, to write anything off patents. Success had now been attained in their business in America, and he believed it would be attained here, and that they would surmount their present difficulties, in spite of the opposition of their discharged servants, who would never return to their employ.

The CHAIRMAN observed that all such items as goodwill and patents were, more or less, "in the clouds" in the balance-sheet, and if they could succeed in earning sufficient profits, his advice to them would be to be contented with moderate dividends, and to reduce the items in question in the balance-sheet by writing off a certain proportion every year. He thought that every matter that was capable of argument had now been dealt with, and he would, therefore, propose the adoption of the report and accounts.

Mr. HARRY HANKEY DOBREE seconded the motion, which was carried by a large majority.

The CHAIRMAN, in answer to a question, stated that Lord Greville did not like the duties cast upon him as Chairman, and therefore resigned, and Sir William Davies ceased to be a Director practically because he had not the necessary qualification.

The retiring auditors were afterwards re-elected, an amendment for the appointment of Messrs. Parkinson, Mather, and Co. (of Manchester) being negatived on a show of hands.

The meeting then separated after a cordial vote of thanks to the Chairman.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322 *&c., &c.*]

GORDON AND FELL (LIMITED).—This Company was registered on January 4th with a capital of £100,000, in £10 shares. The objects are to acquire and take over as a going concern and carry on the business of J. E. H. Gordon and Co. (Limited), electrical engineers, and the goodwill thereof, with the premises where the said business has been carried on, and the plant, machinery, stock-in-trade, capital, contracts, property, and effects of the said business, subject to the debts and liabilities; to acquire and carry on the business of a builder and contractor for public works, of a worker of and dealer in timber, and of a brick and tile maker, and dealer in fireclay and other minerals, carried on by John Fell at Leamington; to carry on the business of electrical engineers in all or any of its branches, and the business of constructing, manufacturing, supplying and maintaining electric light machinery and apparatus both for public and private purposes, and any appliances connected with the production, transmission, distribution, accumulation, and employment of electricity for the purposes of light, heat, motive power, or otherwise; and also to carry on the business of contractors for the construction, maintenance, and working of roads, tramways, railways, waterworks, gasworks, electric light, heat, and power supply works, wharves, canals, piers, quays, &c.

NEW CAPE CENTRAL RAILWAY (LIMITED).—Amongst the objects of a new Company which has been registered under the above title, with a capital of £100,000, in £5 shares, are those of telegraph and telephone engineers, mechanical and electrical engineers, ship owners, manufacturers, &c.

NEW JERSEY METAL REFINING WORKS (LIMITED).—A Company with this title has been registered with a capital of £50,000, in £10 shares, to acquire the business now carried on in the State of New Jersey, U.S.A., by a Company called the New Jersey Extraction Works (Limited), and to carry on the business of smelters, refiners, chemical manufacturers, &c.

Hosted by Google

STEPHENS AND CO. (LIMITED).—This Company was registered on January 7th, with a capital of £20,000, in £1 shares. The objects are to take over as a going concern the business of electrical and general engineer, smith, and boiler maker, carried on by John Stephens, at Cuba-street, Millwall, London, E.; to acquire by purchase from J. G. Statter and Co., of 68, Victoria-street, Westminster, London, S.W., certain machinery, plant, stock, &c., upon the said premises at Cuba-street; to enter into and carry into effect an agreement with a view to the acquisition of the above properties, dated December 12, 1892, and made between John Stephens, of the first part; John Grice Statter, Henry Foote, and Leonard Milne, trading under the style of "J. G. Statter and Co.," of the second part; and Arthur M. Sillar (on behalf of this Company), of the third part; and to carry on the business of electricians, electrical and general engineers and contractors, ironfounders, smiths, boiler makers, and manufacturers of and dealers in all apparatus and things required for, or capable of being used in connection with, the generation, supply, distribution, accumulation, and employment of electricity. John Stephens is Managing Director, with a salary of £400 per annum, and John Grice Statter and Henry Shirley Price are the remaining Directors.

WATERHOUSE ELECTRICAL MANUFACTURING COMPANY (LIMITED).—This Company was registered on the 9th inst. with a capital of £20,000, in £10 shares. The objects are to enter into and carry into effect an agreement between Addison G. Waterhouse and the firm of Waterhouse Brothers, of the first part, James H. Gamble and Francis T. Chambers, of the second part, and Reginald Bolton, of the third part, to acquire any patents, licences, concessions, &c., conferring an exclusive or non-exclusive right to use any invention, and to use, develop, or grant licences in respect of the patents specified in the above-mentioned agreement (further particulars of which are not given), or any other patents or inventions that may be acquired.

MISCELLANEOUS. — FENBY'S (LIMITED), founders, engineers, and machinists; capital £10,000, in £5 shares.——HAYDON AND VAIL (LIMITED), general engineers; capital, £3,000, in £1 shares.

AURORA ELECTRIC LIGHTING AND DISTRIBUTION COMPANY (LTD.).—The first annual return of this Company, made up to October 11 last, has been filed. Forty shares out of a total capital of £25,000, in £1 shares, have been taken up, and the full amount called on the first 35 shares, resulting in the payment of £35. Upon the remaining five shares no calls have been made. An agreement, dated January 2, 1893, between the above-named Company and Charles James Fox, engineer and contractor, states that the said Charles J. Fox has rendered in the past valuable and efficient services towards the said Company, and has also agreed to render such services in the carrying out of various contracts, and it is therefore agreed that the Company shall allot to the said Charles J. Fox 5,000 fully paid-up shares of £1 each, Nos. 926 to 5,925 inclusive, in full satisfaction and discharge of the services above-mentioned, and of all claims and demands in respect thereof.

BIRMINGHAM TELEGRAPH FACTORY (LIMITED).—The annual return of this Company, made up to December 8, 1892, has been filed. The Company was registered on December 31, 1890, with a capital of £50,000, in £10 shares. At the time of making-up, 707 shares were taken up, of which 400 were issued as fully paid, in accordance with the above agreement. Upon the remaining 307 shares, the full amounts had been called, resulting in the payment of £3,010, leaving £60 in arrears.

BLAKEY, EMMOTT, AND CO. (LIMITED).—The annual return of this Company, made up to November, 12, 1892, has been filed. The Company was registered on September 8, 1886, with a capital of £35,500, in £100 shares. At the time of making up, 302 shares were taken up, of which 185 were issued as fully paid in accordance with the above agreement. Upon the remaining 117 shares £50 per share has been called, resulting in the payment of £5,850. In addition to this, £300 has been paid in advance of calls. Edward Blakey holds 36 shares and Walter Emmott 67 shares.

HENLEY TELEGRAPH AND ELECTRIC CONSTRUCTION COMPANY (LIMITED).—At meetings held on December 5th and December 21st, it was resolved and confirmed that the Company be wound up, and Mr. J. H. Stephens, 6, Clement's-lane, was appointed liquidator.

HERCULITE MANUFACTURING COMPANY (LIMITED).—At meetings held on November 17th and December 12th resolutions were passed and confirmed that a reconstruction of the Company is desirable, and that the Company be therefore wound up; that Mr. E. J. Lunnon, 19, Ironmonger-lane, secretary to the Company, be liquidator; and that the liquidator consent to the registration of a new company, to be named the Herculite and Electrical Manufacturing Company (Limited).

KENNEDY STORAGE BATTERY COMPANY (LIMITED).—The statutory return of this Company, made up to December 15, 1892, has been filed. The whole capital of £100,000, divided into 100,000 shares of £1 each, has been taken up, and has been allotted as fully paid, in accordance with the contract dated August 30, 1892, with Patrick Kennedy and Charles Joseph Diss. The shareholders are as follows:—William L. Barker, of New York (6,250); Patrick Kennedy and Charles J. Diss, both of Brooklyn, New York (33,750 jointly); The Doris Syndicate (Limited) (3,300) Herbert W. Hooper (3,000), Ernest Zuccani (2,500), Benjamin G. Lake (2,500), William J. Sutherland (2,500), and George C. A. Kohler (46,200).

LONDON ELECTRIC WIRE COMPANY (LIMITED).—The statutory return of this Company, made up to October 6, 1892, has been filed. The Company was registered in May, 1892, with a capital of £50,000, divided into 5,000 ordinary and 5,000 preference shares of £5 each. At the time of making up, 4,138 preference and 4,451 ordinary shares had been taken up, of which 3,860 shares of each denomination had been issued as fully paid, in accordance with the above contract. Upon the remaining 278 preference and the 591 ordinary shares, the full amount had been called, resulting in the total payment of £4,345.

REVOLVING ADVERTISER COMPANY (LIMITED).—This Company has been registered with a capital of £816, in £1 shares, to acquire an invention, described in Patent No. 14,183, for an improved mechanism for effecting the movement of indicating tablets in railway coaches and other public vehicles. The subscribers include Frederick J. Beaumont, electrical engineer, and John Kent, electrician, the latter of whom is one of the first Directors.

WESTERN COUNTIES ELECTRIC LIGHT AND POWER SYNDICATE (LIMITED).—The statutory return of this Company, made up to September 9th last, has been filed. The Company was registered in April, 1892, with a capital of £25,000, divided into 120 deferred and 380 ordinary shares of £50 each. At the time of making up 41 ordinary shares had been taken up, the full amount called and all calls (£2,050) paid.

WOODITE COMPANY (LIMITED).—At a meeting held on December 8th, at Woodite Works, Mitcham Common, it was resolved that the Company be wound up; and Mr. Henry Godfrey, 9, Southampton-street, Bloomsbury, and Captain Walter Wood, Woodite Towers, Mitcham Common, were appointed liquidators.

CITY NOTES, &c.

ARCAS PLATING COMPANY (LIMITED).—Letters of allotment in the recent issue of capital by this Company have been posted.

BABCOCK AND WILCOX (LIMITED).—The Directors have declared an interim dividend at the rate of 10 per cent. per annum, for the past half-year, payable on the 14th prox.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts fro the week ended January 8th were £998, as against £858 for the corresponding period of last year, being an increase of £140. The total receipts for half-year amount to £998, against £858 in the corresponding period of 1892, being an increase of £140.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of December were £3,600, as compared with £3,420 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons on their Five per Cent. Debentures, due February 1st next, will be paid on and after that date at the banking house of Messrs. Glyn, Mills, Currie, and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announces the payments by warrants on February 1st next, of interest for the half-year ended January 31st on their Four per Cent. Mortgage Debentures. The transfer books will be closed from January 27th to February 1st, both days exclusive.

GEORGE ANGUS AND CO.—The Directors of this Company recommend a dividend of 10 per cent., being the same as last year.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—An interim dividend of 1s. 3d. per share has been declared by the Directors of this Company, payable on the 20th inst.

GORDON AND FELL (LIMITED).—This is the title of a new Company, formed to amalgamate the electrical and contracting business of Messrs. J. E. H. Gordon (Limited), 11, Pall-mall, and the general contracting business of John Fell, Leamington. The share capital of the concern is £100,000, added to which there are 2,000 Five per Cent. First Mortgage "Profit" Debentures of £50 each. The whole of the share capital is taken by the vendors as purchase money. The debentures are repayable after twenty-one years, or redeemable at the option of the Company after five years at 5 per cent. premium. The payments are £2. 10s. on application, £2. 10s. on allotment, £12. 10s. three months after allotment, and £12 10s. six months after allotment. The interest upon these debentures, at the rate of 5 per cent., has been guaranteed (the prospectus states) for five years by the Securities Insurance Company (Limited). The trustees for the debenture holders are Major-General Sir R. Pollock, K.C.S.I., and the Hon. H. Willoughby. The Directors include Mr. J. E. H. Gordon and Mr. John Fell. The secretary is Mr. Henry Sinclair, and the offices of the Company are at 11, Pall-mall, S.W., and at Leamington. After dealing with the number of works carried out by the two firms, the prospectus states that the aggregate of average profits of the two businesses during a certain period has been at the rate of £13,750 per annum. The works, properties, and estates of Messrs. J. E. H. Gordon and Co., taken over by the new Company, have been valued by Sir Henry Mance at £61,500. Application is to be made to the Stock Exchange for the usual quotation in due course. It is estimated that the amount of working capital remaining, after the purchase of the businesses from the vendors and the payment of all liabilities, will be £32,500. The list closed yesterday (Thursday).

LIVERPOOL OVERHEAD RAILWAY COMPANY (LIMITED). — A special meeting of the shareholders of this Company has been held under the presidency of Sir W. B. Forwood. The Directors submitted a resolution to create 12,500 Five per Cent. Preference Shares of £10 each, and to issue 7,500 of these at par, the Chairman explaining that the money was required to carry out the Northern extension, at a cost of £37,000, and to complete the present undertaking. The proposal was adopted.

Hosted by Google

SIAM.—At a meeting of the Siam Electric Light Company on November 13th last a statement was read showing the Company's financial position. It was decided to petition the King of Siam to take over the business, he to pay the shareholders 25 per cent. on their investment.

STOCK EXCHANGE QUOTATIONS.—The Stock Exchange Committee have ordered the additional shares, Numbers 82,441 to 91,240, of Elmore's Patent Copper Depositing Company (Limited) to be quoted in the official list.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Jan. 6, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited) were £3,507.

"THE ELECTRICIAN" BLUE BOOK.

MORE THAN 1,000 PAGES OF RELIABLE MATTER. THE ONLY COMPLETE ELECTRICAL DIRECTORY.

"THE ELECTRICIAN"

Electrical Trades' Directory

AND

HANDBOOK FOR 1893.

SPECIAL NOTICE:—

RENEWED INSTRUCTIONS for 1893 from Advertisers in the 1892 Edition represent, up to January 17, no less than **94 per cent.**

NEW ADVERTISERS represent nearly 30 per cent. over 1892.

SUBSCRIPTIONS to the 1893 Edition represent an increase of nearly 40 per cent., chiefly from Local Authorities and other large users of Electrical Machinery and Apparatus; and from the Colonies and India.

OLD FEATURES of the Book will be thoroughly revised and brought up to date.

NEW FEATURES of interest and value to the Electrical and Allied Trades will be added, and therefore New Advertisers and Subscribers for the 1893 Edition should send in their orders at once.

The Publisher especially requests the immediate return of the printed circulars asking for information from those who have not already sent them in.

DYNAMO.—One MATHER and PLATT'S "MANCHESTER" DYNAMO, No. 5, scarcely used, shunt wound, output 135 volts 70 amperes at 850 revolutions; with absolutely new spare armature for same; packed in case; and foundation rails. A Bargain.—T. MITCHELL AND CO., Engineers, 95, Drury-lane, London, W.C.

FIFTY-FIVE 50-volt ARC LAMPS WANTED; 35 for 5 amperes in seven series of 5 each, and 20 for 10 amperes in four series of 5 each. —HARPERS (LIMITED), Engineers, Aberdeen, Scotland.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER
have a large selection of
SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.
Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

THE ELECTRO-HARMONIC SOCIETY.—SMOKING CONCERT, FRIDAY, January 27th, 1893, at the ST. JAMES'S HALL, RESTAURANT (Banquet Room), Regent-street, W., at Eight o'Clock.

"SILENT" ENGINES (CHANDLER'S PATENTS)

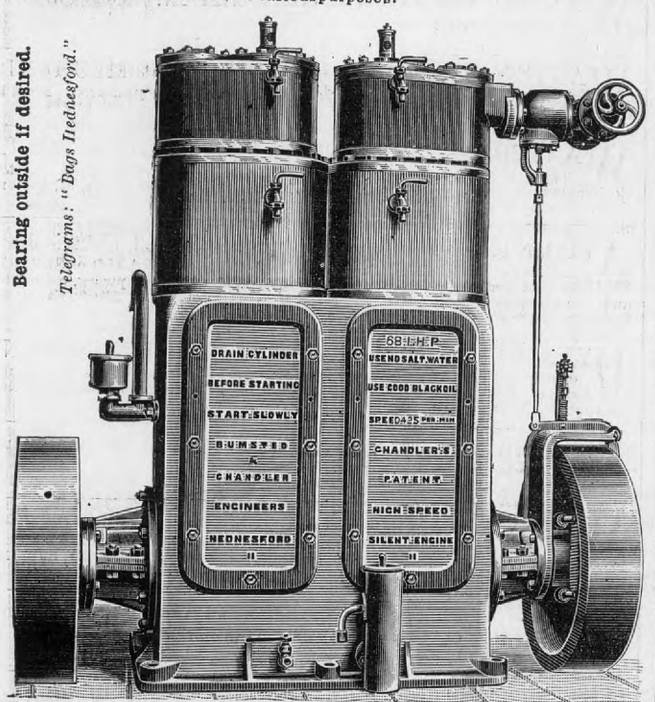
FOR ELECTRIC LIGHTING.

Made in 20 SIZES, with one or two cranks, from 2 to 200 Horse-power, simple compound or tri-compound, giving the highest economy, at speeds suitable for coupling direct to dynamos for THEATRE-LIGHTING, for CENTRAL STATIONS, for SHIP-LIGHTING, and TRAIN-LIGHTING.

Electrical Firms and Shipowners may place perfect confidence in these Engines, as they are the most durable ever introduced, and as economical as any other high-class engine. After prolonged and severe tests (which caused the engines of other makers to break down) these engines were selected for use on ss. "*Teutonic*"; these worked so satisfactorily that they were also selected for ss. "*Majestic.*" Each ship now has 17 engines on board, for various purposes.

Bearing outside if desired.

Telegrams: "Bags Hednesford."



One Electrical Firm has ordered no less than 40 engines in two years, another firm 32, another firm 19, another firm 16, another firm 14, and a large number of other firms have sent many repeat orders. Twenty of the British India Steam Navigation Company's Steamers are lighted by these Engines. All this goes to prove that the Engines are reliable and highly satisfactory. Many are working without lubrication to Cylinders. NO AIR NOR OIL CAN POSSIBLY PASS AWAY TO CONDENSER.

Every part can be got at comfortably when the door is removed.

Speed adjustable while Engine is running. Requires less care than any other Engine known, and uses less oil. **NO OIL IS LOST.** Engine easily understood. No complications Inside. Constructed to stand hard work. The Patent "Safety" Governors are Extremely Sensitive. They are mounted on the Crank Shaft and require no belt to drive them, and are everlasting.

Letter from Superintending Engineer of Sixteen Steamers with these Engines on board, says:—"*All the Engines are working very satisfactorily.*"

CHANDLER CROMPTON COMBINED COMPOUND PLANT.

For SHIP LIGHTING and TRAIN LIGHTING, as supplied to the Cape Government Railways and many Steamers.

BUMSTED & CHANDLER,

Cannock Chase Engine Works, HEDNESFORD, STAFFS.

THE EASTERN TELEGRAPH COMPANY (LIMITED).

NOTICE is Hereby Given, that the FORTY-FIRST HALF-YEARLY ORDINARY GENERAL MEETING of the EASTERN TELEGRAPH COMPANY (Limited), will be held on THURSDAY, the 26th JANUARY, 1893, at One o'Clock in the Afternoon, at WINCHESTER HOUSE, 50, Old Broad-street, London, to receive the Directors' Report and Accounts, elect Directors and Auditors, and transact the ordinary business of the Company.

By order of the Board,
GEORGE DRAPER, Secretary.

London, 17th January, 1893.

By JOHN MUNRO, C.E., & Prof. A. JAMIESON, F.R.S.E., M.I.C.E., M.I.E.E.

NINTH EDITION, Pocket Size, Leather, 8s. 6d.

The NINTH EDITION has again been carefully revised and enriched with fresh matter, including several important communications by leading authorities on Electro-Technics.

LONDON: CHAS. GRIFFIN & Co., Limited., Exeter Street, Strand.

CALVERT'S MECHANIC'S ALMANAC FOR 1893.

(Price 4d.) Contains, besides other valuable matter, "Patents: Some Popular Delusions," by W. LLOYD WISE, Esq., J.P., C.C., Fellow of the Chartered Institute of Patent Agents.

MANCHESTER: JOHN HEYWOOD, Deansgate; and JOHN CALVERT, 99, Great Jackson-street.
LONDON: JOHN HEYWOOD, 2, Amen-corner.

370 pages, 159 illustrations, price 10s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS.

By J. A. EWING, M.A., B.Sc., &c.

After an introductory chapter, which attempts to explain the fundamental ideas and the terminology, an account is given of the methods which are usually employed to measure the magnetic quality of metals. Examples are then quoted showing the results of such measurements for various specimens of iron, steel, nickel, and cobalt. A chapter on Magnetic Hysteresis follows, and then the distinctive features of induction by very weak and by very strong magnetic forces are separately described, with further description of experimental methods, and with additional numerical results. The influence of Temperature and the influence of Stress are next discussed. The conception of the Magnetic Circuit is then explained, and some account is given of experiments which are best elucidated by making use of this essentially modern method of treatment. The book concludes with a chapter on the Molecular Theory of Magnetic Induction; and the opportunity is taken to refer to a number of miscellaneous experimental facts, on which the molecular theory has an evident bearing.

NOTES.

Before the Metropolitan Railway was commenced, Mr. E. A. Cowper was consulted about the use of steam on the proposed line, and he made the suggestion that a "very large" boiler, starting with steam at 250lb., would run nearly six miles and do the necessary work without any furnace or fire. Though suggested, we are not aware that it was seriously recommended, and it was not until 1878 that M. Léon Francq designed his fireless locomotive. This was intended for tramways of moderate length. The boiler contained some 400 gallons of water, and steam at 220lb. Stationary boilers, steaming at a maximum of 242lb., charged the locomotive boilers by passing the steam into them through specially arranged pipes. Locomotives were built at the Hunslet Works, Leeds, and ran with some success on the Rueil Tramway, in France.

The idea essentially was merely one of storage, and now that storage is the desideratum of electrical engineers, Mr. Druitt Halpin's scheme for thermal accumulation described last week by Prof. Unwin at his first Howard lecture, deserves their careful attention. A condensed report of Prof. Unwin's lecture will be found in another column. So far from being a fireless system, it appears to allow the fires to be maintained uniformly, and thus the "stand-by losses" of boilers worked for only a few hours a day may be avoided. It is proposed to raise steam at 250lb.; but what is, perhaps, more important, a considerable body of water will be at the same time raised to 406deg. This water, when the pressure is released, will develop steam during certain working hours, independently of any additional supply of heat which it may receive during that period. It is proposed to use the steam at 130lb. As some form of storage is needed to put the use of refuse destructors on a practical footing, the combination of such furnaces with high pressure boilers seems to be worthy of consideration.

While far better than electrical storage, so far as facility for rapid discharge is concerned, Mr. Druitt Halpin's thermal storage cannot be considered to be quite perfect, for it involves steady wire-drawing; but, no doubt, Mr. Halpin has considered the losses occasioned thereby. These are capable of accurate calculation from well-known thermo-dynamical principles, they are proportional to the fall of temperature and not to the reduction of pressure; superheating might, therefore, be considered in connection with them; the wire-drawing would dry the steam, but no doubt all the pros and cons will soon be made public. It is, however, clear that the use of the steam by successive expansions would be preferable to wire-drawing, and while triple and quadruple expansions for the sake of reducing fuel consumption have been attended with so many losses by friction that many engineers have fought shy of the practice, there would be an undeniable advantage in multiple expansion, where considerations, altogether outside the design of the engines, provide a supply of steam at 250lb. This pressure is modest enough, and the difficulties of carbonisation of lubricants experienced by Mr. Perkins ought not to give trouble.

The discussion on Dr. Fleming's Paper on "Experimental Researches on Alternate Current Transformers" has been brought to a close without the smallest addition to our knowledge of the actual loss incurred in the mains of an alternate current system, on account of the magnetising currents of transformers. It is true that his most interesting Paper does not pretend to deal with the economical considerations of supply, but what of that? Do not discussions at scientific meetings meander round the subject and ramify into the neighbouring problems? Mr. Arthur Wright, whose remarks brought the discussion to a close, thought that even with a transformer of 98½ per cent. efficiency, "there is no room inside a circle of a mile and a-quarter radius for transformers." We are not aware that the advocates of continuous current supply on the three-wire—No! we beg pardon, we mean the compound parallel system—have ever contemplated the supply of so large a district from a single network, without the assistance of dynamotors, as at Oxford, or high pressure charging mains. Looking down the column headed, "Distance of Farthest Lamp in Yards," in our supplement of Jan. 6th, we find that out of nine London Companies who have given us the necessary information, seven work within this radius, and two beyond it; while out of fifteen provincial stations, twelve work within and three beyond it, and two more may shortly be added. These majorities, of course, include a large proportion of alternate current systems. It is little use to further discuss the efficiency of transformers while the efficiency of mains and feeders are neglected. We shall be greatly disappointed if Dr. Fleming does not contribute something to this branch of the subject in his reply.

Hosted by Google

Among our reviews this week we have had to notice two books which we believe to be purely American, but which have been "got up" with more or less care to resemble and to pass off as English. In one case the attempt fails, in spite of a specially-printed title-page pasted in. The book purports to treat of Modern Mechanism. It is a cyclopædia, and gives, no doubt, an excellent account of the subject from an American point of view, without altogether ignoring certain European manufactures. American mechanism is, of course, of world-wide reputation, and no one who desires to be conversant with the whole science and practice of mechanism can afford to neglect the American branch. But we assert that a book published and sold in this country under this title, with no indication on the title-page that it is of American origin, is calculated to cause great disappointment to incautious purchasers. The other book so closely resembles an English work, but for the capital G's and a few minor indications, that ninety-nine persons out of a hundred would take it without hesitation to be a genuine English cyclopedia. It is true that the contents are of a fairly international character, and are likely to be almost as useful to a student, or whoever it is that reads electrical dictionaries, as a real English work; and in this respect it differs widely from "Modern Mechanism." But we contend that the purchaser is likely to be deceived, and may probably be disappointed.

The Merchandise Marks Act was framed with the object of preventing this misunderstanding. We do not for a moment allege any inferiority, nor is the Merchandise Marks Act confined to cases of fraudulent substitution of inferior articles in the guise of better ones. It merely provides that, when an article bears such marks or words upon it as may be calculated to lead a purchaser to imagine that he is buying an English article, it shall also bear a prominent notice by which he may be properly warned. Such a notice, we contend, ought to be given on the title-page of the books to which we allude, and, perhaps, in the preface also. It can hardly be included in the title—but either it should appear in publishers' catalogues, or some means should be adopted to protect the unwary. The printing of books in this country from American stereotypes is the natural outcome of the Copyright Convention. It does no direct harm to the printing trade, as might be imagined, since in no case would these books be produced here, for, if not printed in this manner, they would be simply imported. Our anxiety is for for the misguided buyer and for the indiscriminating reader.

The experiments with an induction coil, described in another column, throw an interesting light upon the character of the currents obtained from induction apparatus. Although the total quantity of electricity discharged by the secondary is the same both on making or breaking the primary current, the electromotive force is greatest, and the discharge quickest, in breaking. Mr. Maclean shows this by using a voltameter in conjunction with a vacuum tube. The fact, however, may be shown in a much simpler manner; for if the knob of a Leyden jar be placed near, though not in contact with, the terminal of an induction coil, and the latter be set working, it will after a short time be found that the jar is highly charged. The high potential induced when the primary is broken is sufficient to cause a brush discharge to the jar, while the potential induced on make has no effect on the charge. The numerical results obtained by Mr. Maclean are not very concordant, but they could hardly be expected to be so. The current measured by the voltameter is the arithmetical mean of a current which varies in a most irregular and altogether unknown fashion; and it must also be remembered that the contact breaker of an induction coil is a very rough piece of apparatus. The average value found for the ratio of the primary and secondary currents is 6,000 to 1. It is interesting to compare this with the ratio of the turns of the two coils. This ratio is not given in the Paper, but for many well-made induction coils it is about 1 to 100.

The Blake Transmitter Patent.—This patent expires to-day. (No. 229, January 20, 1879.)

Coast Communication.—The Royal Commission on Lighthouse Communication with the Shore has concluded its interim report, which will be laid before Parliament on the 31st inst.

Hull.—The municipal central lighting station was opened with due ceremony on Monday by the Mayor. The three-wire system with batteries has been adopted, and the station is of 10,000 light capacity.

Taunton.—At the last meeting of the Town Council the Electric Light Committee reported that it had been decided that an application should be made to the Local Government Board for leave to borrow £16,000, instead of £14,000 as originally estimated. The report was adopted.

An Electric Railway Across the Simplon.—A proposal was on Tuesday brought before a number of Swiss bankers in Geneva for the construction of a rack railway, operated by electricity, to traverse the Simplon. The cost of the line is estimated at £1,600,000, and the period of construction at four years.

Forthcoming Life of Werner von Siemens.—Messrs. Asher and Co. inform us that they will publish shortly an English translation of the "Recollections of the Life of the late Werner von Siemens." The German original, published in December last, ran most successfully through two editions in the course of a few weeks.

Telephone Litigation in Belgium.—The State and the Bell Telephone Company are "in interference" in Belgium regarding the taking over of the Belgian telephone system by the Government. According to the contract, the State has power to take over the telephones at the end of ten years. The State, says *Industries*, holds that this term has expired, while the Bell Telephone Company argues that it does not expire till the end of this year.

"Cause of Fire Unknown."—We take from the *Electrical World* of New York a syllogism, which we recommend to the notice of Captain Simonds, in connection with the Regent-street fire of November last:—"Electricity is something the exact nature of which is unknown; the origin of that fire is something the exact nature of which is unknown; therefore, as things equal to the same thing are equal to each other, the origin of that fire is electricity."

The Electric Lighting of Gedney's Channel.—According to a Reuter's telegram, dated New York, January 14th, the ice has broken the lamps and lanterns of the electric lighting system in Gedney's Channel, which is consequently left without beacons. It is expected, however, that the damage done will be speedily repaired. A description of the system em-

Hosted by Google

ployed in Gedney's Channel will be found in *The Electrician*, Vol. XXVIII, April 22, 1892, p. 663.

Richmond.—At the meeting of the Town Council last week the Electric Lighting Committee reported that the works were proceeding satisfactorily and with all possible promptitude, having regard to the inclement weather. Councillor Thompson stated that the works ought to have been finished by December 8th. There was a penalty of £8 a day if the contractors failed to do this. But they had only just commenced. An amendment "that the penalties be enforced" was lost, and the report was adopted.

Electricity in South Africa.—Mr. Bennett H. Brough lectured on Wednesday evening, before the Society of Arts, on the "Mining Industries of South Africa, as shown at the Kimberley Exhibition," and stated that the gardens there were lighted by electricity. At the De Beers diamond mine the electric light is used both at the surface and underground, the greater part of the levels and the main ladderways in the mines being illuminated in the same way. The most important colliery in the Transvaal is situated 20 miles from Johannesburg, and is lighted by electricity.

Cable Interruptions and Repairs—

Cable.	Interrupted.	Repaired.
Singapore-Saigon	Jan. 17, 1893	Jan. 19, 1893
Cayenne-Vizeu	Sept 24, 1892	—
Senegal-Pernambuco	Dec. 26, 1892	—

An error occurred in our report of cable repairs last week. The paragraph should have read—

Cable.	Interrupted.	Repaired.
St. Thomé-Loanda	Nov. 24, 1892	Jan. 11, 1893
Mozambique-Laurenço Marques ...	Jan. 5, 1893	Jan. 12, 1893

The Popp Mains.—A burn-out recently occurred on the electric light mains of the Popp Company running along the Boulevard Beaumarchais, where the *canalisation* consists of bare copper bars placed in cast-iron troughs filled with bitumen run in hot. At corners and curves the troughs are made of cement, and, for some reason, the insulating compound kept in a semi-fluid condition at these points, with the result that the conductors gradually became displaced and short-circuited, setting the *canalisation* alight. The system, says *L'Industrie Electrique*, will, therefore, probably be altered once more.

The Corrosion of Lead-Covered Cables.—It has been known for many years that lead pipes frequently suffer from corrosion when laid in certain kinds of earth, while certain waters eat away the inside. During the discussion on a paper on "Cables" at a meeting of the students of the Institution of Electrical Engineers, Mr. A. T. Weightman mentioned the case of the Loch Katrine water at Glasgow. He stated that this water contained free carbonic acid, which attacked the lead, and that the fault was corrected by treating the supply with chalk. He proposed, therefore, to embed lead-covered cables in chalk.

The Association for the Improvement of Geometrical Teaching.—A meeting of this Association was held on January 14th, at University College, Gower-street, W.C., the chair being taken by the Master of St. John's College, Cambridge. Mrs. Bryant, D.Sc., gave a model lesson on geometry to a class of about 20 ladies. After an adjournment, Papers were read by Mr. G. Heppel, M.A., on "The Use of History in Teaching Mathematics," and by Mr. F. E. Marshall, M.A., on "The Teaching of Elementary Arithmetic." The attendance was larger than usual, and interesting discussions followed the lesson and the Papers.

Electric Traction.—At the last meeting of the Pembroke Commissioners, Mr. Clay, solicitor, attended, and submitted particulars of the proposed introduction of electricity as motive-power for the tramways in the district. It was resolved that the Board should consent to the introduction of electricity, subject to an undertaking by the Company that a clause should be introduced giving the township engineer power to direct where the posts should be placed, and to have them shifted if necessary, and also that they might be used free of cost for lamps if the Commissioners saw fit to light the township with electricity.

Railway Rates.—In a circular to the members of the London Chamber of Commerce, it is stated that the Railway Association have appointed a Committee of General Managers to meet the traders and discuss any grievances alleged to have arisen from the new rates and arrangements, and in order that proper representations may be put before the Committee, and also to afford the basis for any other steps it may prove necessary and possible to take, members are asked to kindly supply particulars of any grievances they may have under the new scale of rates, and also to attend a special general meeting to be held in the Council Room to-day, at 12 noon.

Accumulator Patent Litigation in Belgium.—The Brussels Courts have just given a decision in the action brought by the Société l'Électrique, La Compagnie Franco-Hollandaise (in liquidation), and M. Julien against the Société Franco-Belge Tudor. The plaintiffs originally asserted that the Tudor accumulator was an infringement of the Faure and Julien patents, but ultimately restricted the issue to an alleged infringement of the Faure patent. The Court, in a lengthy judgment, held that the plaintiffs' case was not made out, and admitted the claim of the Tudor Company to compensation for the damage done to its business by the seizure of its apparatus and the publicity given to the action.

Obituary.—We regret to record the death at Sydney on the 14th inst., after a very short illness, of Mr. E. C. Cracknell, the Superintendent of the New South Wales Government Telegraphs. Mr. Cracknell was born at Oxford in 1831, and proceeded to Sydney about the year 1855, where he organised the telegraph system in New South Wales, and remained at its head until his lamented decease. His last visit to Europe was in 1885, when he attended the Telegraph Conference at Berlin. He took great interest in the Australian volunteer movement, and held the rank of Major in the New South Wales Volunteers, especially devoting his energies to the defences of Sydney Harbour. He had a large circle of acquaintances, both in Europe and Australia, by whom he will be deeply regretted.

The Hopkinson Three-Wire-Patent Case.—The following is extracted from *The Times* of Tuesday:—

SIR: With reference to the report of this case and the statement at the end thereof that the Judge suspended the injunction for six months, our clients, the Westinghouse Electric Company (Limited), of 4, Victoria-mansions, 32, Victoria-street, the owners of the patent in question, feel that a wrong impression may be conveyed. They, therefore, would like it known that they agreed to this suspension of the injunction as a concession and out of regard to the great public inconvenience that would have been caused by a summary stop being put on the electric lighting of the St. James's district. The St. James's Company have, however, to continue the account of profits which the judgment has awarded the plaintiff during the suspensory period.—Yours truly,

FAITHFULL and OWEN, Solicitors for the Westinghouse Electric Company (Limited),

11, Victoria-street, Westminster, S.W., Jan. 16th.

The City-road Windmill.—Messrs. Carwardine's windmill, which has been used for the electric lighting of their flourmill, besides other work, has been attacked by the County Council as a sky sign, and now the Ecclesiastical Commissioners, as freeholders of the land, have obtained an injunction restraining its further use on the ground that it is an erection contrary to the terms of the building agreement. A rather interesting experiment is thus brought to an end. We understand that the plant gave Messrs. Carwardine every satisfaction while it lasted, the power obtained being sufficient to light their premises with 27 16 c.p. lamps and 3 arc lights. The storage cells are in excellent condition, and have given no trouble whatever. At the time the injunction was granted Messrs. Carwardine were about to erect a motor, to be driven by the accumulators, for the purpose of hoisting sacks.

The American Telegraphs.—The annual report of the Postmaster-General of the United States (Mr. Wanamaker) for the year ended June 30, 1892, contains the following:—

"It was said long ago that the telegraph must be a monopoly, and so is the postal system; but the difference is that one is operated for private gain and the other for the public good. The Government follows a settler across the plains and into the mines. The telegraph goes where it can find paying business only; and so it falls out that only a sixtieth part of the people of the United States employ the telegraph. Practically, so far as the public is concerned, there is but one telegraph company. This enormous business, producing gross revenues nearly one-third as large as the

Hosted by Google

entire revenue of the post office department, increases every year. I have never, as you know, advocated the purchase or construction of telegraph lines by the Government. My proposition is to make a contract with some telegraph company to connect post offices by telegraph or telephone, commencing with the most important offices and proceeding gradually in the order of probable usefulness. I would contract with a telegraph company to perform the service with its own operators for a fixed sum per message."

The Chicago Exhibition.—It is announced by the officers of the department of electricity at the World's Fair, says the *Western Electrician*, that the manufacturers of "electric belts," "magnetic rings" and the like will not be allowed to display their wares in the electricity building. Chief Barrett has decided that these impostors do not come within the scope of any legitimate application of electricity, and they will, therefore, be excluded.——The fuel being used in the Exhibition buildings is said to be a very soft coal, the smoke from which is rapidly discolouring many of the white buildings. But as soon as the necessary arrangements are completed, oil will be the only fuel used. A line of 6in. piping is now nearly completed to bring petroleum from Indiana to the storage reservoirs on the gronds. The length of this piping is between 70 and 80 miles. The reservoirs will contain more than a day's supply. The Exhibition Authorities hope to commence using oil in February.

Nelson.—On Thursday, December 22nd, the municipal supply of electrical energy to Nelson was commenced. The engineer and contractor is Mr. Thomas Barton, of Blackburn. Steam is generated principally by means of hot air passing from the gas retorts, the hot gases being passed between the tubes of an ordinary boiler; this heat is sufficient to raise ample steam for the present engine at 60lb. pressure. The central station is 35ft. by 20ft. by 20ft., and at present contains one central valve engine capable of generating 80 I.H.P. at 460 revolutions. The capacity of the dynamo is 360 amperes at 120 volts. The distributing mains are on the 2-wire system. The main cables are insulated with vulcanised rubber, and are carried upon vitrified porcelain bridges in cast iron conduits, distributing and tapping boxes are placed at intervals in the usual way. The sub-mains are insulated in the same manner, and are carried inside iron tubes lined with glass. The majority of the shops have adopted the light which the Corporation have offered to supply at cost price for three years. The centre of the town is lighted by arc lamps.

The Brighton-Rottingdean Electric Railway.—Under the Bill for powers to construct an electric railway from Brighton to Rottingdean the promoters seek to be authorised to construct a railway just under three miles in length, commencing near the Paston-place Groyne, at Brighton, thence proceeding along the beach and foreshore, between high and low water-mark, about 100 yards in front of the cliff to its termination on the seashore at Rottingdean, whence a pier is to be erected. The railway is to be constructed on the extraordinary gauge of 24ft., while the platforms and carriages are to "be placed at such an elevation as to be safe from interruption by the sea." The capital of the proposed company is set down at £15,000, with power to borrow a further sum of £5,000. The first Directors of the Company are given as Mr. Edward Overhall Blackley, Mr. John Jackson Clark, Mr. Magnus Volk, and Mr. Steyning Beard. The time sought within which to complete and open this railway is five years from the passing of the Bill; and from the clauses fixing the maximum rates and tolls, it appears that only passengers and small parcels will be carried over the line.

Cement for Pipe-Joints.—The use of Portland cement is recommended, says the *Journal of Gas Lighting*, for steam joints, and is said to answer every purpose, besides being exceedingly cheap. Herr Adolph, of Mayence, is putting upon the market packing-rings made of cotton tubing filled with cement, in assorted sizes. These can be used for making manhole and other flange joints by the simple process of wetting them thoroughly, laying them in place, and screwing up; taking care to keep a uniform pressure over the whole ring. A still cheaper joint can, however, be made with neat cement alone; the cotton casing being superfluous. It is only necessary to gauge the cement into a thick paste with water, until it is of such a consistency that when daubed on a vertical wall it neither falls off nor flows down. The flanges are to be cleaned of grease and dirt, and the cement applied evenly, in quantity according to the area to be covered. The joints thus made are to be screwed up carefully until the thickness is reduced to about $\frac{1}{8}$inch, when they are to be left for the cement to set. The screws are then finally tightened, and the edges of the joint plastered over with a little fresh cement, which two or three hours after is wiped over with a wet cloth or brush. Socket joints can be made in the same way.

The Junior Engineering Society.—Recent visits of this Society have been to the Central Telegraph Office and the General Post Office, St. Martin's-le-Grand, and to the Millbank-street and Eccleston-place stations of the Westminster Electric Supply Corporation, both of which were very largely attended. In connection with the former visits excellent arrangements for the guidance of the members through the extensive premises were made by the authorities, and every feature of engineering interest was pointed out. In the Central Telegraph Office the instrument galleries, telephone departments, battery rooms, pneumatic tube apparatus, the engines producing the vacuum and pressure actuating it, and the boiler room were seen. In the post office were shown the stamping machines, mechanical lifts and engines working them, the electric light installation now in course of extension, and various models of postal appliances, including one of a mail railway car with gear for taking on and throwing off the bags. At Millbank-street and Eccleston-place the members were shown round by the respective resident engineers, Mr. Newington and Mr. Grimshaw; Prof. Kennedy, past-president of the Society, who was announced to receive the party, being prevented at the last from doing so by an unexpected engagement in Scotland. At each station every point in the arrangement and working of the plant was explained. In regard to steam supply it was noticed that at Millbank-street Babcock and Wilcox water tube boilers were fitted, while at Eccleston-place boilers of the marine type were in use, which, it was stated, worked so satisfactorily that the most economical coal consumption of any electric light station had been obtained. The regularity of the load on the station had assisted to this good result.——The eighth anniversary dinner of the Society will be held in the Queen's Salon of the Holborn Restaurant, at 6:30 p.m., on Saturday, January 28th, Dr. John Hopkinson, F.R.S., President, in the chair.

Windsor.—The Corporation who are endeavouring to electric light Windsor and Eton are still in conflict with the authorities. The difficulties under which they labour, through certain shortcomings in respect to initial capital, and the conditions of the Provisional Order, are in themselves a sufficient obstacle to cope with; but beyond that, it seems that they will have to fight the anti-electric element in the Council over every step they take. The Company having been fined a week or two ago for breaking up the streets without permission, it was thought that the Corporation would be content with this vindication of their rights, and allow the Company to proceed with their scheme in peace. At the last meeting of the Council fresh complications arose, the Company having opened more streets without due notice and permission. At the Town Council it was argued that until the Company had complied with Board of Trade requirements, the Company did not legally exist, and no countenance could be given to its acts. The discussion waxed warm and even slightly personal, until a compromise had to be arranged. The motion to give the permission for the cutting of a trench was replaced by a proposal to refer the question to the Streets Committee for consideration and report, and the vote given upon this was eight on each side. This created a fresh difficulty; but it was overcome by the Mayor giving his casting vote for the proposal. The Company contemplate starting running on Monday next. The sequel to the latest action of the Corporation is curious and instructive. Determined to have the electric light, for which the fittings have been up some time, one firm has resolved to set up their own installation, and have obtained for this purpose a gas-engine and a dynamo. Very opportunely, in view of the difficulties attending the introduction of the electric light into the town, the Windsor and Eton Scientific Society are organising an electrical exhibition in connection with their annual meeting.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 299.)

25. Buoying a Bight.—It is sometimes necessary to buoy the grapnel rope if it is found in lifting cable that the strain becomes too great for the rope. In such cases, instead of risking breakage of the cable or rope it is safer to stop lifting and attach grapnel rope to buoy. The bight of cable then remains suspended on grapnel while ship proceeds to another position and lifts cable again. The illustration (Fig. 89) is from an instantaneous photograph on board the "Electra," taken while grappling and for the purpose of showing the effect of a heavy strain on the dynamometer, the sheave of which is seen to be raised so that the rope passes almost in a horizontal line underneath it. The strain in lifting a bight of cable is due more to the pulling of the cable from both sides towards the bight than to the weight of cable alone. A certain percentage of slack varying according to the depth, is payed out at the time of laying for the purpose of facilitating lifting during repairs; but even with a liberal allowance, spread as it is uniformly along the route, there is a good deal of shifting of cable on both sides towards the ship when she lifts a bight. Say the ship raises a bight of type D in 1,500 fathoms laid with 10 per cent.

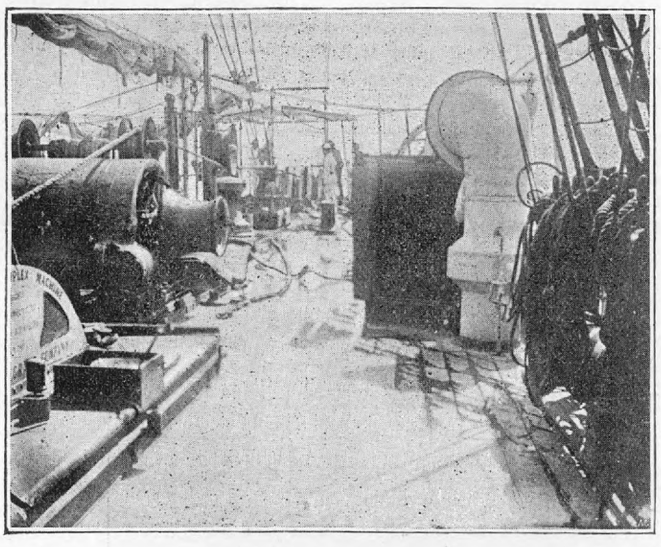

FIG. 89.—Grappling. Dynamometer Showing Heavy Strain.

slack. To raise this to the surface cable must be lifted off the ground or pulled towards the ship from a distance on each side of bight equal at least to double the depth, or a total lifting or moving of about six knots of cable. This adds to the strain about as much again as the weight of cable alone, and means about seven tons' strain on the grapnel rope when cable is nearing the surface, which is equivalent to five tons per square inch on the cable itself. Beyond this there is a margin of two or three tons per square inch before breaking strain is reached; but, as the cable gets older, this margin diminishes.

Sometimes on a repair circumstances necessitate putting in a piece of intermediate in too great a depth. In lifting this again on any subsequent repairs in the same spot the strain will be unusually great. Suppose a length of type B laid in the moderate depth of 700 fathoms. In raising this the cable would be put to a strain of four tons per square inch, and the grapnel rope would have to bear quite nine tons, which is very near its breaking strain. The proper size cable of type D laid in this depth would only be subject to two and a-half tons per square inch, or about three and a-half tons on the grapnel rope.

Whether due to this cause or too little slack, or the cable being buried, the grapnel rope is buoyed as in Fig. 90 if the strain is considered unsafe. The sketch for want of space, does not represent the correct curve taken by the cable when lifted. After buoying the bight in this manner the ship proceeds to a position further on, at a distance equal to double or half as much again as the depth of water, and lowers grapnel again. This time a cutting and holding grapnel is used and the knives set to cut the cable on the side next the buoy, the other end being lifted inboard and tested. On returning to the buoy and getting grapnel rope connected to drum again, the bight is easily lifted, as half the strain has been removed by cutting.

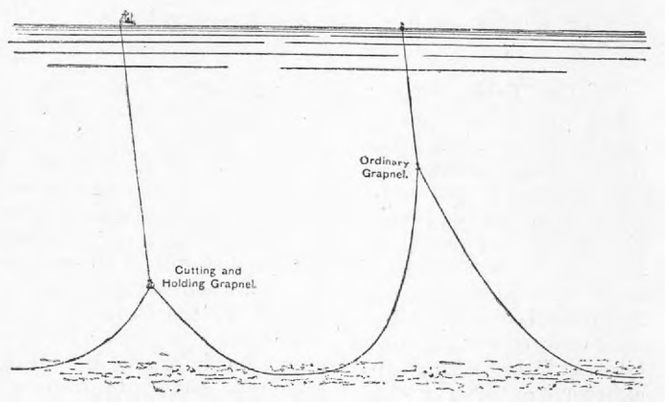

FIG. 90.—Bight Buoyed. Ship Cutting.

When grappling the second time and raising to cut, ship must be kept moving a little towards buoy so that no strain comes upon the latter; otherwise the cable which it supports may be dragged away and pull the buoy under the surface, when it may collapse. On a repair to one of the Australian cables where a bight was buoyed in this manner, the ship while lifting the second time to cut, was carried by a surface current away from the buoy. The latter was seen disappearing below the surface in time to avert its sinking too far, the ship being immediately steamed against the current and kept moving up towards the buoy to relieve the strain. Buoys have also been known to sink in a strong tideway.

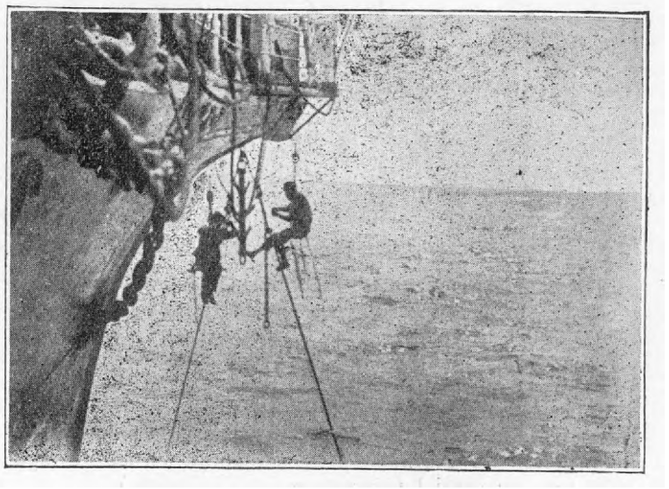

FIG. 91.—Cable Hooked on Shackle of Grapnel.

Another way of effecting the same object is to buoy the second bight and then run between the two bights and part cable with a simple cutting grapnel; such a grapnel is of the old five-prong type with knife edges fixed in the seat of each prong. Or it may be possible to raise cable between the two bights without cutting below the surface.

The most difficult conditions to perform this under are when two or more cables cross each other near the point or lie very close together. In that case two bights can be buoyed and the centre raised to the surface and examined before cutting. In

one instance on raising the second bight to the surface and cutting, the end next buoy was about to be thrown overboard in the usual way, but on the chance of its being a piece of abandoned cable the end was retained, and on picking up was found to be separate altogether from that on buoy, being, in fact a piece of cable abandoned on a previous repair which was thus all recovered.

A curious case of raising cable occurred some little time ago on board the "Electra." The cable came up as shown in the photograph (Fig. 91), on the shackle of the grapnel, not being caught by the prongs at all. The illustration shows the manner of letting down two men over the bows seated in boatswains' chairs, to put the chain or rope stoppers on each side of the cable.

26. The Cable Ship "Mackay-Bennett."—This steamer, owned by the Commercial Cable Company of New York, is employed in the maintenance of the Company's system in the Atlantic and European waters. The two Atlantic cables of this company from Ireland to Nova Scotia represent together 4,732 miles, the two from Nova Scotia to the States 1,337 miles, and the two European cables connecting Ireland with England and France 839 miles, or a total of 6,908 miles. Of the four other companies owning Atlantic cables only two, the Anglo-American Telegraph Company and the French Company, have their own repairing steamers (the "Minia" and the "Pouyer-Quertier"), the other companies when repairs are needed, hiring either one of these or one of the large cable manufacturing companies' steamers at a cost of from £160 to £240 per day.

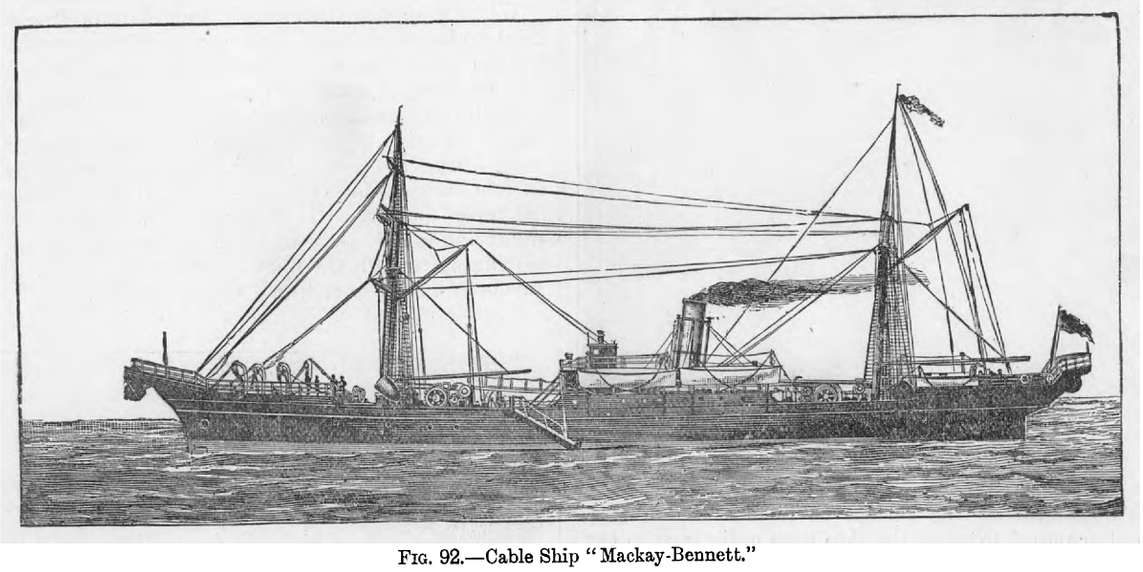

FIG. 92.—Cable Ship "Mackay-Bennett."

The "Mackay-Bennett," launched in September 1884, was built at Govan on the Clyde, in the yard of Messrs. John Elder and Co., and measures 270ft. by 40ft, by 24ft. 6in. depth moulded. Her tonnage is 1012·92 net registered and 1,700 gross registered. The illustration (Fig. 92) has been kindly lent by the Company's General Superintendent in England, Mr. G. H. Bambridge, to whose courtesy the writer is indebted for the accompanying details. In the design of this steamer special pains have been taken to give her good steering and manœuvring qualities. In addition to the usual stern rudder, a second rudder is fixed at the bow inside the line of the stem, which can be worked by a hand-wheel. This very useful addition enables a course to be kept when going astern (frequently required in repair work), in easing strain on cable or in fetching or getting clear of a buoy or splice. Steam steering gear on Messrs. Muir and Caldwell's system is fitted in the wheel-house aft, and can be operated from either of two wheels, one amidships and one on the poop. A hand-wheel is also fitted aft as a stand-by, giving a third means of steering independent of steam. Her manœuvring qualities are still further increased by the use of Brown's patent hydraulic reversing gear, already referred to in these Papers as fitted on board the "Electra." As the "Mackay-Bennett" is a twin-screw steamer and Brown's reversing gear is fitted to each engine, there is not much time lost in turning her round either way. Bilge keels are also fitted which minimise the rolling in heavy weather.

The engines are compound surface-condensing, with cylinders 25in and 50in. diameter. On her trial trip a speed of 12·3 knots was attained, the engines developing 2,190 I.H.P. The coal bunker capacity is 750 tons.

Three cable tanks are fitted, having a total capacity to loading lines of 385 knots or 710 tons of deep sea cable 1in. in diameter. The fore tank, No. 1, is 20ft., No. 2 30ft. and No. 3 28ft. in diameter, and the mean diameters of the cones are respectively 6ft. 2in., 7ft. 2in. and 6ft. 2in. The fore and aft tanks can be loaded to a height of 10ft., and the tank amidships to 14ft. At these heights the fore tank holds 60 knots, the midships 195, and the aft tank 130 knots of the above type of cable. The tanks are all in connection with pumps in the engine-room, by means of which they can be flooded with water or discharged, as required.

Steam cable gear capable of dealing with repairing work in the deepest waters of the Atlantic, is fixed both forward and aft. That in the fore part of the ship, used chiefly for grappling and picking-up, has a single drum driven by a double-cylinder engine with inclined cylinders, fitted with clutch for single or double purchase, and a brake for paying-out with the engine thrown out of gear. The brake is controlled by a hand wheel and screw. The aft gear is driven by a similar engine with clutch for throwing out of gear when paying-out with the brake. The bow and stern sheaves are fitted underneath the working deck or platform, as in the "Faraday." The testing room is situated at the forward end of the ship's bridge, and underneath it. Lord Kelvin's sounding air-tube navigational machine, and James's submarine sentry for indicating depths while in motion are carried, and the ship is also supplied with Messrs. Johnson and Phillips' sounding machine for deep-sea work.

For trimming purposes the "Mackay-Bennett" is built with a special cellular double bottom running the whole length of the vessel, which can be utilised for water ballast to the extent of 300 tons.

The equipment of this handsome vessel is completed with an electric lighting plant consisting of two Siemens dynamos each with a normal output of 90 amperes at 110 volts. These are driven by a pair of Tangye's engines, the light being distributed throughout the ship, and night operations facilitated by deck-light reflectors fitted with six and eight incandescent lamps.

The faults chiefly met with in the Atlantic are caused by ships' anchors.

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Continued from page 246.*)

Commencing now to give our attention to the sparking that takes place at commutators particularly, it may be well if at the outset we consider what are the conditions that usually obtain with a commutator of a well-made dynamo. For simplicity's sake, we will refer only to the case of an ordinary two-pole machine, of a closed-coil type. Such a case is represented diagrammatically in Fig. 7 herewith. It will be observed that a horizontal field is shown; and to avoid confusion, we will assume this throughout our remarks, together with the north pole-piece on the right-hand side, and the direction of rotation of the armature, as shown by the curved arrow. Each segment *c c* is connected up to an armature coil *b b*; and the latter may be considered to be coils round a ring as in Gramme winding; or else as each carried round the whole diameter of the core, as in drum winding.

Now, it is well known that in the course of the generation of current and electromotive force under the above conditions, the coils of the armature winding, which are nearly or quite horizontal, as at *w x*, generate the most potential: for they are here including or excluding the horizontal lines of force of the field at the greatest *rate*. Hence each segment of the commutator connected to coils in this position will have its potential raised above that of the one below by an amount equal to the potential gathered by the coil or section of winding that connects them. Thus there will be a

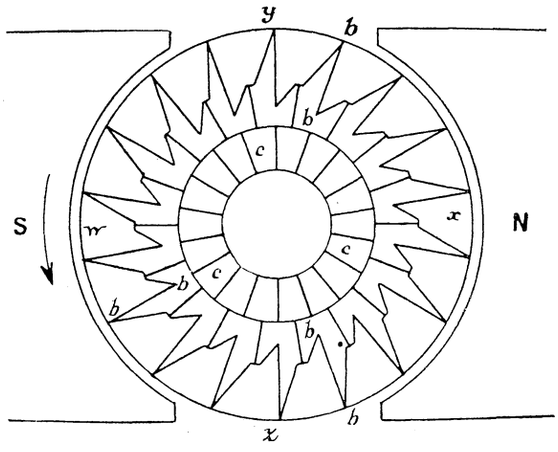

FIG. 7.—Diagram showing Commutator, Armature Winding and Field.

maximum potential difference between adjacent segments at the *sides w* and *x*. But the coils that lie in planes nearly or quite vertical, as at *y z*, are practically not including or excluding lines at all: hence they generate no potential. Consequently, there will be a minimum, or practically no potential difference between their commutator segments; and the potential difference between any two adjacent segments will increase as the plane of their connecting armature coil leaves the position normal to the lines of force of the field, and approaches a position parallel to them; and *vice versâ*.

Now, a plane in or about a position containing a line through *y x* (Fig. 7), is known as the plane of commutation; for it is herein, as the armature coils successively arrive into it, that they change the direction of the current within them, or are "commuted." It needs to be clearly understood, however, that this plane is one through the *armature winding* only, and not through the commutator, at least necessarily. The segments of the commutator may lie in or about the same plane as the coils to which they are connected, as in the case of Gramme winding, or with drum winding (approximately) when the parallel conductor bars on the armature run straight out to the lugs of the commutator. Or the segments may be at right angles to their connecting armature coils, as with drum winding when the connection with the commutator segments is made from the interior of the end-winding—that is, from the middle of the cross connectors instead of from their exterior ends. This interior connection was exemplified by the Hopkinson and Eickemeyer end windings illustrated and described

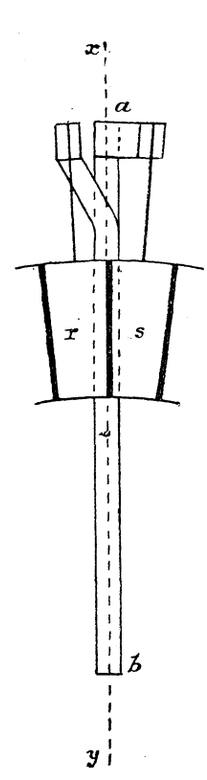

FIG. 8.—Plane of Coil between two Commutator Segments.

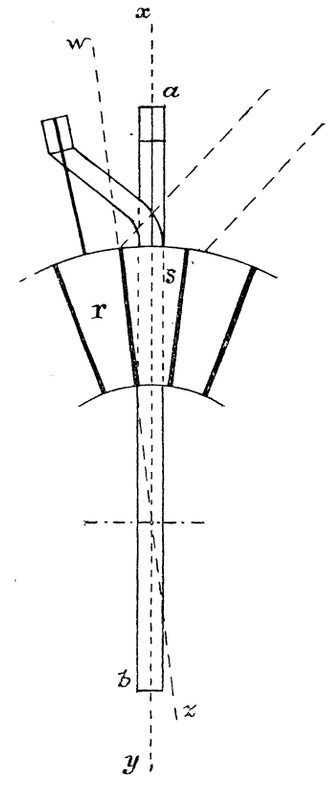

FIG. 9.—Plane of Coil Cutting through one Commutator Segment.

in another article (see *The Electrician* for December 5, 1890, pp. 135 and 136); while various outside end connections may also there be found. Figs. 8 and 9, will, however, make the matter yet more clear. In both of these *a b* is an armature

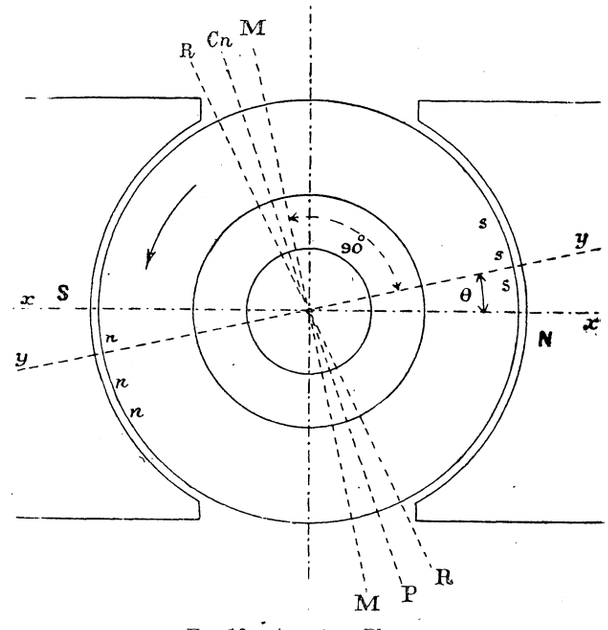

FIG. 10.—Armature Planes.

coil seen endways, and lying in a plane *x y*. But in the former we find this plane cuts exactly *between* the segments *r* and *s* to which it is connected; while in Fig. 9 it cuts through the segment *s*; the latter is perhaps more usual in dynamo construction.

Hosted by Google

It is from this point, however, that we shall now need somewhat to enlarge. Having thus far made allusion to what is termed the plane of commutation, it will be necessary to expatiate more fully in this direction. For in order to arrive at a good understanding of our subject as a whole, we may assume four other such planes. These, together with the plane of commutation, are represented variously in Figs. 10, 11, and 12, and may be enumerated as follows :—

(1) The plane of commutation.

(2) The neutral plane or plane of non-sparking.

(3) The plane of requisite reversal.

(4) The plane of maximum and minimum potential through the commutator.

(5) The plane of maximum and minimum potential through the armature.

We thus find that, as we had five orders of sparks, so we have here five different planes. To these we may now give our attention. In the first instance, however, we will merely briefly consider them, so as in some degree to define each one, postponing a fuller discussion till afterwards, when we

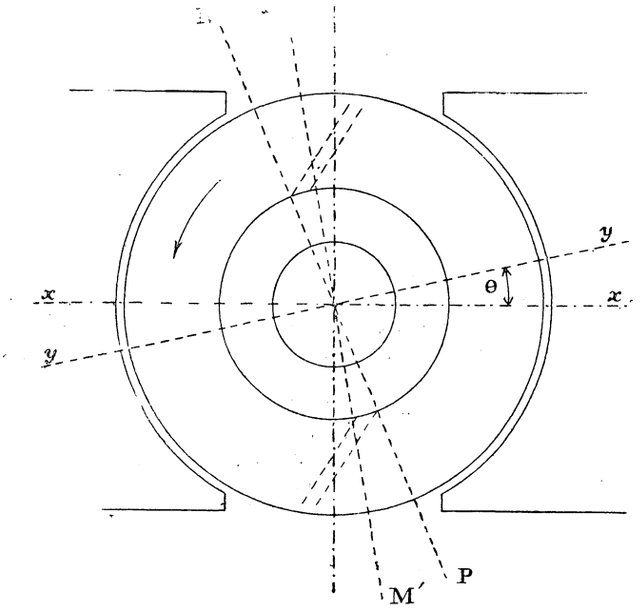

FIG. 11.—Commutator Planes. Brushes above and below.

may take them all, more or less, into consideration in conjunction with one another, in the same manner, in fact, as we dealt with our category of sparks. Thus, to touch on them in order, we return once more to the plane of commutation, which comes first in the list. This plane is indicated by the line Cn P in Figs. 10 and 12.

As the act of the reversal of current in a coil cannot take place—that is, from full strength in one direction to full strength in the other direction—without *some* expenditure of time, however small, this plane of commutation may be considered as occupying that position wherein the coils, as they arrive into it, have an infinitesimally small amount of the reverse current commencing to flow in them. Practically, this is, of course, tantamount to saying that it occupies a position where there is *no* current in the coils. But this is the exact instant of change, that is, of commutation ; and such a definition has the advantage of being, as it should be, definite. Further, however, it has to be understood that this plane is *not a fixed element* in the dynamo. For its position is governed by the brushes, which are moveable. But it follows these with some degree of elasticity none the less, which we shall discuss later in our remarks.

Now, whereas the plane of commutation had to do with the armature coils, the neutral or non-sparking plane, the next in our order, has to do with the commutator. This is indicated by the letters N P in Figs. 11 and 12. As its name implies, it is that plane through the axis of the commutator which contains the points on either side, where, if the brush points are resting there, no sparking occurs. Unlike the last, it is a more or less *fixed* element in a dynamo—that is, normally and with a steady load. It does not move with the brushes ; but, contrariwise has to be found by shifting the brushes to and fro, and so by experiment noting the position where no sparking takes place. Of course, in some dynamos there is no such position ; or, at the best, only a point of minimum sparking. But to this we shall return.

The third plane is distinct from the first two in more than one respect. We have termed it the plane of requisite reversal. It is indicated by the line R R in Figs. 10 and 12, and is an element of the winding, and not of the commutator ; and is, moreover, a normally fixed element. As regards its fixity, in fact, it accords with the neutral plane of the commutator : and, depending entirely on construction and the method of connecting up the armature winding with the commutator, it *might coincide* with the neutral plane. This latter, however, would only occur when, as in Fig. 8, the plane of the coil divides the two segments to which its ends are connected ; or, more

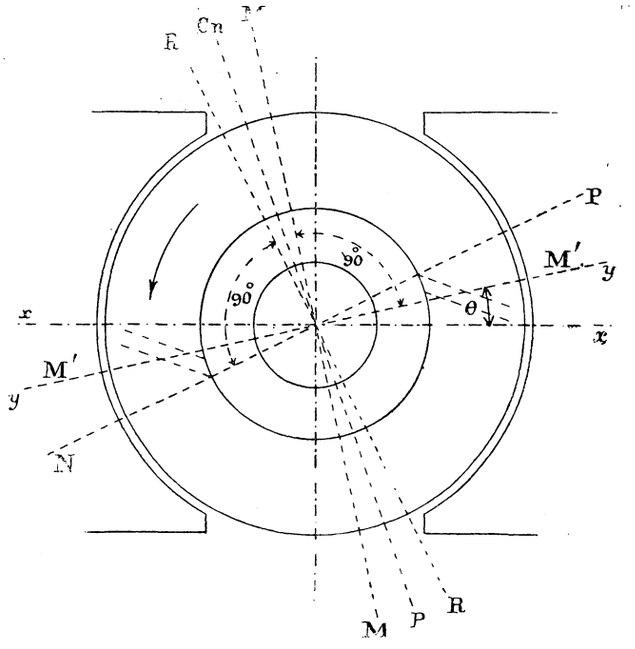

FIG. 12.—Armature and Commutator Planes. Brushes at the sides.

accurately, when it passes through the edge of the receding segment *r*, as shown. Otherwise, as in Figs. 9 or 12, the two planes will be distinct, though at a fixed and invariable angle with each other. It is necessary to defer a more full explanation of this third plane, until we can consider them all conjointly.

Like the second, the fourth plane is an element of the commutator. It is represented in Figs. 11 and 12 by the line M′ M′, and is that plane through the axis of the commutator which contains the points on either side where there are respectively the maximum and minimum potentials. When the brushes are at the non-sparking points, then this fourth plane would lie somewhat behind, as shown in the diagrams. It is normally a fixed element not moveable directly with the brushes ; and with a steady load, should not vary in position.

(To be continued.)

Austrian Telegraphic Statistics.—The following figures are from the report of the Minister of Commerce, recently issued regarding the working of the telegraphs during 1891, as compared with 1890 :—Number of telegraph offices in 1891 was 3,905, and in 1890 3,801. Number of telegrams in 1891 was 9,661,297, and in 1890 9,081,631.

SOME RECENT EXPERIMENTS WITH AN INDUCTION COIL.*

BY MAGNUS MACLEAN.

The total quantity of electricity set in motion in the secondary circuit of an induction coil by the make in the primary is equal to the total quantity set in motion in it by the break in the primary; but the durations are quite different. Fig. 1 will help to illustrate this point. A B represents the time during which the inverse-make current lasts, and B C the time during which the direct-break current lasts, D E the maximum of the inverse current, and F G the maximum of the direct current. The area A D B, which represents the total quantity of the inverse-make current, is equal to the area B F C, which represents the total quantity of the direct-break current. That the quantity set in motion by the break is equal to the quantity set in motion by the make was experimentally proved by Faraday, and subsequent theory and experiments have corroborated the fact.

If, however, there is a non-metallic gap in the circuit, whether of air at ordinary pressure, or at much-reduced pressure, as in vacuum tubes, the *break* impulse causes a flow in one direction, and the make causes either no flow or a much less flow in the opposite direction; because the short intense impulse of the former breaks down the resistance, while the comparatively long and less intense impulse of the make either does not break down the resistance at all, or only does so to a much less degree, so that the effective resistance is much greater in one direction than in the other.

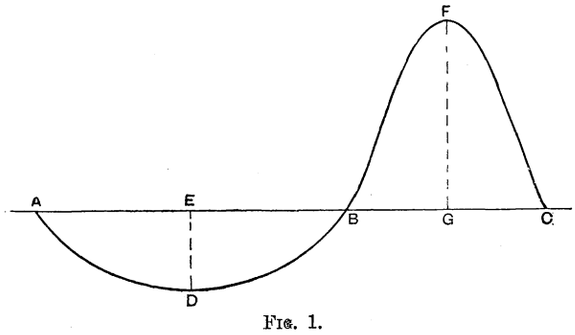

FIG. 1.

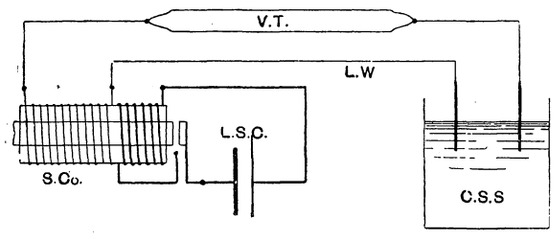
To obtain the average difference of quantity of electricity set in motion in one direction above that in the other, a copper electrolytic cell was put in circuit with a vacuum tube and the secondary coil of a small Ruhmkorff coil. The solution in the cell was copper sulphate of density 1·17 with one-half per cent. of commercial sulphuric acid added. The electrodes were No. 36 B.W.G. copper wire 0·012 centimetre in diameter, and they were immersed in the solution as little as possible, to give the best current density for the deposit. To obtain the best result the total immersed area of the cathode plate should be 50 square centimetres per ampère. Fig. 2 gives a diagrammatic representation of the arrangements. The



S.Co. Secondary Coil. L.S.C. Large Secondary Cell. L.W. Loss Wire. C.S.S. Glass Vessel, containing Copper Sulphate Solution. V.T. Vacuum Tube to indicate Current.

FIG. 2.

experiments were mostly performed by Mr. Alex. Galt, B.Sc., F.R.S.E., in the Physical Laboratory of the University. It was imperative that the small and very light electrodes should be manipulated with the greatest care. Before each experiment they were carefully cleaned, dried, and weighed, and at the end of the experiment they were detached singly from the connecting wires, plunged at once into a vessel of clean water to remove any adhering copper sulphate, and immediately placed in the folds of thick, dry blotting-paper, where they were thoroughly dried; then they were again weighed. Table I. gives the results of seven of the experiments. The shortest time any of these experiments lasted was one hour and ten minutes, and the longest time four hours and five minutes.

* Abstract of a Paper read before the Philosophical Society of Glasgow.

The average current showed by all these experiments is one-sixth of a milliampere. It is noticeable that the gain is in six of the seven experiments greater than the loss—the one exception being June 8th. On looking up the laboratory note book, no remark is found regarding this experiment, to, in any way, explain why in this respect it differs from all the other experiments.

Table I.

Date.	Time the experiment lasted in seconds.	Loss of one wire in milligrammes.	Gain of other wire in milligrammes.	Current in milliamperes calculated from the gain wire.
1892.

,, 16	14,700	0·58	0·8	0 1819

REMARKS.—The average current given by these seven experiments s one-sixth of a milliampere.

An electrolytic cell with copper electrodes was now inserted in the primary, and Table II. gives the results of three experiments. The current in the secondary coil calculated from the gain wire was found to be slightly less than a sixth of a milliampere, and the average current in the primary, calculated from the gain plate, a little less than an ampere. The mean ratio between the two currents was 6,000.

Table II.

Date.	Time experiment lasted in seconds.	Gain of plate in Primary circuit in grammes.	Current in Primary calculated from gain plate in milli-amperes.	Secondary Circuit.			Current in Primary ÷ current in Secondary
				Loss of one wire in milli-grammes.	Gain of other wire in milli-grammes.	Current calculated from gain wire.	
1892.							
July 4	10,080	3·0229	914·3	0·33	0·55	0·166	5,496
,, 5	10,800	3·10465	876·4	0·62	0·43	0·121	7,220
,, 6	10,800	2·08885	589·0	0·58	0·40	0·113	5,222

REMARKS.—Taking the average of these results, it is found that the current in the primary is 6,000 times that in the secondary, which is a little less than that found in Table I., viz., one-sixth of a milliampere.

A long thermometer tube full of solution of copper sulphate was now inserted in the secondary circuit instead of the vacuum tube. The resistance of this column of copper sulphate solution would be comparable to the resistance of the vacuum tube. A "Kelvin" multicellular was put at the terminals of the vacuum tube while the experiment was going on. It indicated 165 volts. This would give the effective resistance of the vacuum tube to disruptive discharges as $165 \div \frac{1}{6000} = 1$ megohm. In this case there was no air gap in the secondary circuit. The whole circuit was completed by metal and copper sulphate solution. The results obtained are inconclusive, as sometimes both electrodes showed a slight loss, and sometimes they indicated neither gain nor loss. Some experiments were also tried with an air gap instead of a vacuum tube, the results obtained being similar to those obtained with the vacuum tube. A few experiments were also tried with nothing in the secondary circuit but the secondary coil and the electrolytic cell. In every case both electrodes showed loss.

It would be interesting to try these experiments, commencing with the largest air gap that the secondary coil could spark across, and gradually diminishing the air gap till there is metallic contact. A beginning has been made in this direction, but no definite results have as yet been obtained.

GAS v. ELECTRICITY FOR ILLUMINATING PURPOSES.*

BY S. A'COURT.

Dealing with the public lighting of the streets and squares of London, the author referred to the fact that no two parishes were alike in the quantity of light per unit area of streets of equal size, nor did they agree in the actual positions of the lamps. In St. Pancras the arc lamps were on posts in the centre of the main thoroughfares; while Westminster was content with gas-lamps in the middle of the roads, and along the edges of the pavements.

* Abstract of a Paper read before the Civil and Mechanical Engineers' Society, January 5, 1893.

Hosted by Google

He thought it would be admitted that the tendency of the age is towards better public lighting. He acknowledged that gas-lamps had lately been much improved in respect of their light-giving power; and the reflectors fitted to the street-lanterns distribute the light well. The three and five-burner lights in Westminster consume 30 and 50 cubic feet per hour respectively, which, at 3 candles per cubic foot, means 90 and 150 c.p. The author had not been able to discover any proof of the makers' claim of 270 c.p., or 5·4 candles per cubic foot, for the 50ft. burners. Arc lamps burning with 10 amperes and 45 volts had been tested photometrically, and found to give 1,500 c.p. at 45deg.

While, for small streets, gas-lamps of 12 c.p., with those of 90 c.p. at crossings and refuges, will give sufficient light, yet, when important streets are taken, the number of high-power gas-lamps required to give proper illumination means a large initial outlay and a heavy bill for running expenses. A 10-ampere arc lamp complete, with post and lantern, costs £18. 10s.; a 50ft. gas-lamp complete, with post and lantern, costs £14. 11s. The contract price per arc lamp per annum for current, cleaning, carbons, and repairs in London and other towns is £26 on the all-night schedule. A 50ft. gas-burner on the all-night schedule, with gas at 2s. 2d. per 1,000 cubic feet, will cost £23. 8s. for gas alone, or £25 per lamp per annum with cleaning, &c. This is paying the same price for practically one-tenth of the light. It has been found that, to secure good lighting, there are required on both sides of the street, 10-ampere arc lamps, placed at a height of 25ft., and at a distance not exceeding 150ft. apart, measured from lamp to lamp on the same side. When streets are more than 50ft. in width it is necessary to reinforce the lighting with arc lamps on central refuges. In order to give an equal lighting effect with gas, it is found that high power lamps have to be placed in groups of three on refuges, and erected about 50ft. apart along the sides of the even 40ft. streets. Roughly speaking, yet making every allowance for gas, five 50ft. gas burners are required as against every 10-ampere arc lamp. On this basis, the first cost of each, for equal lighting effect, works out to electricity 1 to gas 3·9; and running expenses, 1 to 4·8. In small streets, where lamps serve only as buoys to mark out the channel, gas is cheaper than incandescent electric lamps of equal power (12 candles). But before long we shall be wanting better illumination of small streets; and then it may be found that, if the power of the lamp is raised to 50 candles, electricity can compete, and that favourably.

EXPERIMENTAL RESEARCHES ON ALTERNATE CURRENT TRANSFORMERS.

The following is an abstract of the discussion on Dr. Fleming's Paper, which took place on Thursday evening last week at the Institution of Electrical Engineers. Speakers whose remarks are prefaced by an asterisk have returned their proofs revised.

DISCUSSION.

Prof. FITZGERALD, in resuming the discussion, said that he had attended the meeting in order to make some remarks upon some letters that passed between Prof. Ayrton and himself some years ago in connection with the question of the eddy currents that would be produced in the windings of tranformers. He was sorry to say he was not practically acquainted with the subject very much, but he thought that it would possibly be worth while to call the attention of makers of transformers to the conditions under which eddy currents would be produced The letters were written in March, 1891, in connection with a discussion on the efficiency of transformers then going on. It seemed to him that those engaged in the discussion had not paid attention to a warning which Lord Kelvin had called attention to as to the eddy currents which would be produced in the thick wire of a transformer if it was sufficiently thick. The point that Prof. Ayrton wrote to him about was upon this very question as to how it happened that although there was induction tending to produce a current *round* copper coils there was no induction tending to produce eddy currents *in* the coils. The answer was very simple. Lines of induction *within* the copper ring would produce a current of electricity *round* it. A difference of potential would only be set up in the thickness of the copper itself if the lines passed *through* its mass. The thing that was really of interest was the question as to whether, in order to avoid this eddy effect, the thick wire should be wound outside. He thought that in a perfect closed circuit transformer the driving circuit, whichever that might be, ought undoubtedly to be on the inside. Taking leakage into account it was, generally speaking, best to keep the thick wire coils as far away as possible from the core. Then came the question, whether if they had a hundred, or a thousand, or a million alternations per second, the same thing held. It did not hold accurately, but for a hundred alternations per second, or for ordinary transformer work, he thought there was very little doubt that it did. He was even not sure that the eddying in the thick wire coils was of any real importance. It was Lord Kelvin who called attention to it, and he took refuge under the ægis of his name in saying that it was worthy of consideration. Another thing he was quite certain in saying at the present moment was of no importance yet might at some future time be of importance—what would happen if they multiplied their alternations—suppose they ran up to millions per second? What would the electric force then come to with alternations at the rate of a million per second? The electric force would become very large, something like a million of million times what it would be with one alternation per second; and consequently if they had ten millions per second, they would be coming to a quantity which would very rapidly wipe out the 10^{-21}, and they found in Leyden jar discharges in which they had alternations at the rate of millions per second, the lines of force due to electric displacements, which Maxwell supposed to exist, became of importance. The Hertzian wave was generated. Therefore, if their alternating dynamos ever came to the point of alternating at the rate of tens of millions per second, they would have induction produced in all circuits in the neighbourhood; but until they did use those very rapid alternations he supposed it was not worth while paying attention to the matter.

*Mr. WEEKES said that experiments made at the works of Messrs. Johnson and Phillips had shown that they could neglect the eddy currents in the thick wire; he did not think that it made very much alteration whether they put the thick wire inside or the thick wire outside. Mr. Weekes went on to describe some experiments made at the Central Institution on the effects which followed switching a big condenser off a 100-volt circuit, and they had come to the conclusion that the whole phenomenon of the high potential difference left on the condenser depended on the arc at the switch. They also experimented on the electric arc. They had an ordinary arc which was regulated by hand, and there was a coil in series with it with a moving iron core, so that they could draw the core out and increase or decrease the self-induction. With the core right in, the lag was 47deg.; they then gradually drew the core out, and it decreased to 21deg. They found that if the arc was made of hard carbon the result obtained was altogether different. In fact, instead of the angle decreasing as they pulled the core out, it actually increased. At first they could not quite understand that, and thought it could not be the self-induction effect. The volts on the hissing arc were higher than the volts on the steady arc. Analysing these results they got the following peculiar result:—With the arc silent the electromotive force required to overcome the self-induction of the arc was 12·5 volts, and the electromotive required to overcome the resistance and the back volts of the arc was 33 volts. But with the hissing arc, and the same current of 14·9 amperes, the self-induction rose to 40 volts, and the back E.M.F. + C.R. fell to 22 volts.

*Prof. PERRY said he had been asked by the President to say something about the drop in transformers, that part of the drop due to magnetic leakage. Until the President sent him a note to the effect that he (the President) thought the members of this Institution would like to hear a short explanation of how the drop occurred, he thought that every member of the Institution was already aware of the reason. He had already published what he thought was a simple enough explanation, but perhaps the Paper had not been read. He had proved in a Royal Society Paper that in all calculations on transformers except one, namely, where they wanted to calculate the current supplied to an unloaded transformer, it made no difference whether they took into account hysteresis, eddy currents, and so on; the results were the same as if constant permeability were assumed. Assuming this, and no magnetic leakage or condensers or choking coils, everybody knew that the result was "the secondary current is the same as if it were produced in a circuit of resistance $R_1 (N_2/N_1) + R_2 (N_1/N_2)$ by the primary voltage V_1". Now, the simplest way of defining *magnetic leakage* was to say that a fraction of the induction due to the primary current escaped the secondary coil, and a fraction of the secondary escaped the primary. Let the sum of these fractions be called x. Evidently, then, the leakage produced the same effects as two little choking coils would do, inserted in the primary and secondary circuits. Hence R_1 and R_2 were no longer mere resistances, but contained self inductions. In fact, "the secondary current is the same as if it were produced in an imaginary circuit of resistance $R_1 (N_2/N_1) + R_2 (N_1/N_2)$, and self-induction $M x$ by the primary voltage V_1." This was quite an easy rule to remember. M was the mutual induction, or $M = N_1 N_2 \frac{a \mu 4\pi}{\lambda 10^9}$, where a = section of iron in square centimetres, μ = say, 2000, λ = average length of induction lines in iron. In a 1,500 watt Mordey transformer, $M = 3{\cdot}22$, $R_1 = 27$ ohms, $N_1 = 460$ turns, $R_2 = {\cdot}067 + \rho$, where ρ = external resistance of secondary, being 10 ohms at full load. The time-constant s of a circuit, meant its self-induction divided by its resistance, and here it is $3{\cdot}22\ x \div (2{\cdot}7 + 19{\cdot}17\ \rho)$. Its effect was to diminish the current $200\ s^2 \pi^2 f^2$ per cent. when not too large, and to produce a lag of $360\ sf$ degrees. Here f was the frequency. Evidently the drop due to leakage was proportional to the square of the load. Taking $x = {\cdot}01$, drop at full load in this Mordey is $5{\cdot}567 \times 10^{-5} f^2$ per cent., and lag was $0{\cdot}06 f$ degrees. He was only putting in other language what had been published by him two years ago. He referred to a series of experiments made by Prof. Ayrton on the increased drop with greater frequency in Mordey and Swinburne transformers, and pointed out that the effect in the Swinburne was not necessarily greater, although x was greater, because in the Swinburne M was less, and it was the term $M x$ which was important The fundamental fact was that any induction for either coil which escaped the other was exactly as if they had a little choking coil in the first.

*Mr. HAYCRAFT said there was one point of considerable interest towards the end of Dr. Fleming's Paper. Mr. Mordey had already referred to it. It was that of current rushes and rises of pressure in transformers on switching on. At the Central Institution last year they were using a Ferranti alternator, the frequency being 188 on a circuit consisting of a transformer shunted by a condenser. The secondary of the tranformer was open, and an electrostatic voltmeter was placed across it. The condenser circuit was broken accidentally. It was immediately afterwards re-made. They found that the fuses had gone. The same thing

Hosted by Google

happened afterwards with a smaller capacity. Subsequently whilst some experiments were being made by Mr. Mather, who was transforming up from 50 to 2,000 by a Mordey transformer, and the current was being supplied at very low frequency by a Gramme machine used as an alternator, the fuses suddenly went, and the electrostatic voltmeter fell to zero. This occurred twice, and on examination they found that the brushes of the Gramme were loose. The transformer was a Mordey, excited by current drawn from two opposite points of the Gramme armature, which was running as a motor, and the Gramme field-magnets were separately excited by three or four cells. In one of the cases the voltmeter was seen, and the observer stated that the electrostatic voltmeter rose to a little above 2,000 and then fell to zero. In all their experiments they were transforming in the opposite direction to Dr. Fleming—namely, transforming *up* from 50 to 2,000 volts. He had made some further experiments with Messrs. Woodhouse, Bailey, and Clift. A set-up dynamometer was used to detect current rushes. The rushes were so violent that the movement of the pointer could be heard all over the room. He might mention that this Gramme current was not like the ordinary alternating current; at any rate, the electromotive force curve was not a sine curve. He took the ratio of the maximum of the E.M.F. to the square root of the mean square. The maximum was simply the electromotive force across the brushes, the square root of the mean square given by the Cardew voltmeter on the main; the ratio was 1·95. They next substituted a Ferranti alternator, and repeated the experiment. The frequency was 144; the low volts were made 50 on open circuit. A spark gap was adjusted to 2,270 volts; it sparked on making. In another case the gap was tested to 2,350 volts alternating without sparking, but at the 166th make a spark passed. The gap was across the secondary of the transformer. This was one of several such experiments. A set-up low-reading electrostatic voltmeter on the primary terminals showed no rise of pressure in any case. He might note that at the frequency of 144 there were practically no rushes of current except, of course, when sparks passed. Their general conclusion was that current rushes in the primary were very frequent at low frequencies; at 100 and above they could hardly detect them. Also that the effect does penetrate to the secondary, producing considerable rises of pressure.

* Mr. SPARKS said that the rush of current was first noticed, to his knowledge, in 1886, but no measurement of intensity of the rush was made until that made by Dr. Fleming in 1891. Mr. Mordey pointed out at the last meeting that the rush was most likely owing to the defect of some special type of transformer. Now the rush was most noticeable in a transformer in which the iron was worked at a high induction.

If they took the five transformers mentioned by Dr. Fleming, the induction was very high indeed. He thought Dr. Fleming's explanation of the cause of the rush was the right one. They had made since 1890 tests by the split dynamometer method; they agreed so completely with Dr. Fleming's, that there was no doubt that ordinary electrical people would see that extremely practical results could be obtained with care and selection of the instrument.

* Mr. ARTHUR WRIGHT said one valuable thing about Dr. Fleming's Paper was that it was written without much introduction of mathematics, thus showing how much could be done in alternating-current work without any reference to the self-induction coefficients or the sine curve mathematics of the old school; the introduction in their stead of permeability, and the mean induction, he believed, was all that was necessary for practical purposes. Self-induction ceased to be an understandable term when the sine curve went out. As he designed the Ferranti 1892 transformers, he was very glad to find that the measure of the watts came out very nearly as calculated. In the 20-H.P. transformer, he designed it to have 1·4 per cent. iron loss. He saw Dr. Fleming found it equal to 1·3. He believed this must be due to there being more iron put into the transformer than he designed. He thought it was rather unfortunate that Dr. Fleming should have taken the 1885 5-H.P. size. Certainly it was the worst transformer Mr. Ferranti had ever built. If Dr. Fleming had taken the 10-HP. and the 15-H.P., and made as complete tests as with the 5-H.P., he would have marvelled at Mr. Ferranti's great skill in designing in those days when nothing was known about the loss in iron. The great improvements in modern transformers were apparently entirely due to the adding of more copper. In an 1892 20-H.P. there was something like four times as much copper as one of 1885. Dr. Fleming mentioned the centre of the "Hedgehog" core having an induction of 10,000. He supposed that meant maximum induction; he should like some information on the point, for that seemed abnormally high. He also mentioned that about 30 cubic centimetres in most transformers meant one watt loss. From his (the speaker's) experience he found it generally took 120 or 110 cubic centimetres to give one watt loss. Dr. Fleming hoped that very soon they would be able to get 90 per cent. at 1-10th load; this seemed only a question of money. The way to design transformers had been known a very long time, but it was the excessive cost of the high efficiency transformer that was the difficulty; to diminish that 1½ to 1 per cent. loss would almost double the cost of the transformer. However, it seemed to him that even with the 98½ efficiency transformer there was no room inside a circle of a mile and a-quarter radius for permanently connected transformers, owing to the continual iron loss. The 20-H.P. high-efficiency transformer with its 1¼ mile feeder actually costs in up-keep £50 per annum. He thought that Dr. Fleming's Paper ought to bring the fact more prominently before engineers, that it was of little use going in for higher efficiency transformers, and that they had better study cutting them out when not required. He had been fortunate enough to supply a town on the two systems, and he knew that it took 25lb. of coal per unit sold on the high pressure system; while it now took on the low pressure system only 9lb. working in the same area, and supplying the same number of units. That must show that something ought to be done at once to improve the efficiency of the alternate current system if it had to live against the direct current competition.

BOOKS, &c., RECEIVED.

"Annual Report of the Commissioner of Patents for the year 1891." (Washington: Government Printing Office.) 800pp., 4to.

"Some Observations upon the Conductivity of a Copper Wire in various Dielectrics." By F. Sanford. (California: Palo Alto University.) 40 pp., paper covers. Price 50 cents.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 20th.

LONDON CHAMBER OF COMMERCE.

12 noon. Meeting at Botolph House, Eastcheap, to discuss the new Railway Rates, Sir A. K. Rollit, M.P., in the chair.

SOCIETY OF ARTS.

8 p.m. Howard Lecture II. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S

OLD STUDENTS' ASSOCIATION.

8 p.m. Meeting at the Central Institution. Paper to be read: "Central Station Notes," by W. Brew and P. G. Ledger.

ROYAL INSTITUTION.

9 p.m. Evening Discourse:—"Liquid Atmospheric Air," by Prof. Dewar, F.R.S.

TUESDAY, January 24th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed:—"Gas-Power for Electric Lighting," by J. Emerson Dowson, M.Inst.C.E.

WEDNESDAY, January 25th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Fine Arts in Relation to the Sanitary Condition of our Great Cities," by Wyke Bayliss, F.S.A.

THURSDAY, January 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Presidential Address by W. H. Preece, F.R.S.

FRIDAY, January 27th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "Japanese Magic Mirrors," by Prof. S. P. Thompson, F.R.S.; (2) "The Perception of Colour," by W. F. Stanley, F.G.S.; (3) "Recent Determinations of Molecular Refraction and Dispersion," by Dr. J. H. Gladstone, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read: "The Disposal of Town Refuse by Burning, and the Application of the Heat thereby Generated," by Arthur S. Butterworth, Stud.Inst.C.E.

SOCIETY OF ARTS.

8 p.m. Howard Lecture III. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Just Perceptible Difference," by Francis Galton, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

HOPKINSON'S THREE-WIRE PATENT.

The judgment which was delivered by Mr. Justice ROMER on Saturday last establishes for the present the validity of a patent for one of the most important inventions in connection with the distribution of electrical energy. We purposely refrain from calling it an important patent, for now that it is worth avoiding there is but little difficulty in avoiding, or perhaps it were better to say evading it. It may seem strange that we should contemplate the deliberate evasion of a patent which is admitted on all hands to embody in the most honest manner a deliberate and clear invention of high importance, an invention, too, of one of our foremost and most respected men. Hardly less strange was it to find in the Court an array of experts engaged in dressing up various bits of ancient history to look like anticipations. Engineers, professors, and electricians were ranged against one inventor who had been, if anything, too early in the field. Some explanation was needed to account for the quibbling about arcs and alternators by men who might well have been expected to acknowledge the patent, and to pay reasonable royalties without grudging. The explanation is not far to seek. Dr. HOPKINSON was permitted by one of those odd expedients of law to play the part of a plaintiff, and not only to sustain it throughout, but to bring with him an important array of retained counsel, the whole strength of the Chancery bar. Long ago the patent had been sold to an American company, who have established a branch in this country. With their legitimate business we have nothing to do, it being quite outside the present subject; but they bought this patent from Dr. HOPKINSON for the purpose of levying royalties. It was a perfectly simple business transaction, and we have nothing to say against it. They were not the plaintiffs, for if they had been the defendants could have secured the important counsel by their prior retainers. Thus Dr. HOPKINSON became plaintiff. The exact

Hosted by Google

position was lucidly explained by Sir RICHARD WEBSTER in his opening speech. "The patent in question is now equitably "owned by the Westinghouse Company, but the legal estate "is still vested in Dr. HOPKINSON, and the Court of Appeal "has decided that the action should be brought in his name." This being the situation, it was not surprising that the associated supply companies should have made an effort to resist the tax. Having lost the fight it is at least satisfactory to know that the Westinghouse Company do not intend to throw London into darkness, nor do they intend to enforce the usual penalty that the apparatus used by the defendants shall be delivered up to them. All that the supply companies have to do is to disconnect the middle wires from the dynamos, and if they please to use a small battery, to take the balancing current. As a matter of fact, the two load curves of the St. James and Pall Mall Company are practically identical, and only a very few amperes pass along the middle wire to the station.

The temporary cessation of hostilities which followed immediately upon the production by Mr. J. D. F. ANDREWS of his diagram of the Sauchiehall installation was naturally considered by many to be only a prelude to the complete collapse of the action. In the end, however, the plaintiffs recovered from their surprise, produced most damaging rebutting evidence, and, as was the case with the dog which, "to gain his private ends, went mad and bit the man," it was the Sauchiehall anticipation and not Dr. HOPKINSON's patent that broke down. In spite of the manifold defects of English Patent Law and the manifest absurdity of submitting cases, which in nine instances out of ten involve but a small modicum of law and a large number of extra-legal technicalities, to the judgment of a non-technical gentleman learned in the law, it cannot be gainsaid that substantial justice has been meted out up to the present to the leading electrical patentees. On the one hand the Courts have decided that the Edison patent which contained the claim for "a high resistance filament of carbon within a receiver made entirely of glass, from which air has been exhausted" completely covered the invention of the incandescent lamp. On the other hand, the claims of GAULARD-GIBBS, BRUSH, and LANE-FOX, to have invented parallel distribution by means of alternate-current transformers, compound winding, and constant potential distribution respectively, have obtained but scant success. And the success which has now crowned Dr. HOPKINSON's endeavours to make good in the Law Courts his title to the invention of the Three-Wire System of Supply—a title which has never been seriously disputed outside their precincts—is yet another instance of our English propensity for obtaining correct results from imperfect data and by cumbersome methods.

Patent specifications are not, as a rule, remarkable for lucidity, unmeaning verbiage as well as vague claims abounding. But it is impossible to read the specification, an abstract of which we printed in our issue of November 4th, or to look at the figures illustrating the text, without a frank admission that we have here disclosed in all the plainness of every-day Anglo-Saxon the essential features of the modern three-wire system of distribution, in which arc lamps and motors and electric heaters, Mr. CROMPTON notwithstanding, are merely by the way, one in short which is intended to be used, not to run half a hundred lamps in a factory or a couple of spasmodic arcs at an exhibition, but to supply current to a number of houses connected to an extensive network of conductors. To imagine oneself "as in 1882" is a somewhat difficult feat, but no fair-minded electrical engineer who takes the trouble to perform it, is likely to deny that the idea of using three wires in the manner described by Dr. HOPKINSON was at that time both novel and useful. As Mr. Justice ROMER points out in the judgment, which will be found in another column, "it is a significant fact that Prof. SILVANUS THOMPSON (one of the defendant's witnesses) for the purpose of a lecture about this time prepared a diagram showing all the principal and newest systems or methods of lighting which were known or occurred to him, and yet it never occurred to him to suggest a system like the plaintiff's." Had the conflicting testimony of the "skilled witnesses of the greatest distinction," to which the judge alludes, succeeded in utterly confusing him, probably neither the experts nor anyone else would have been surprised. Such being the case, it would seem as if a system, which is liable to such abuse, were in some need of repair. We are constantly being told that inventors, or rather patentees, should be encouraged by all possible means, though for our own part we do not altogether see the necessity; but be that as it may, they should certainly be protected. If a little more common sense and considerably fewer legal abstrusities were present in our patent law, and the Court were invariably assisted by expert technical assessors, there would be fewer exemplifications of the so-called "glorious" uncertainty of the law, and patent cases might possibly depend rather on matters of fact that on the powers of legal athletes. As exhibitions of dialectical skill of a remarkably high order, actions for infringement are not to be surpassed, but they always leave upon the lay mind an uneasy sense that the validity of the patent in dispute is quite a subordinate item of the performance.

As an illustration of the desirability of having expert assessors on the Bench, we cannot do better than glance at the line of argument taken up by Sir HORACE DAVEY in his opening speech; a line of argument which, notwithstanding its great ingenuity, would not have availed him much in the presence of competent electricians. The opening sentences of Dr. HOPKINSON's specification state that the patentee's improvements relate principally "to maintaining the electromotive force in a system of conductors for an electric supply at a fixed potential," and that "if it be desired to maintain the potential constant at the delivery end, it is necessary to increase the potential at the supply end as the current increases." Further on we are told that the speed of the engine may conveniently be controlled "for the purpose of keeping the potential on *service main* conductors constant"; and, further on still, the use of *feeders* is alluded to. Even the improvement disclaimed—a meter—and the very title of the original patent—"Improvements in Distributing and Measuring Electricity. . . "—point the same way, namely, to a parallel house-to-house distribution. Nevertheless it was solemnly argued for the best part of two days (at how much cost per minute we should not like to say) that there was nothing in the specification which was not equally applicable to series arc lighting. The patentee, it was said, described an instrument for measuring "quantity of current." Well, what if he did? "That was the very thing that was wanted in a series system," in which it was also urged that "feeders" and "service mains" and "constant potential" were quite ordinary incidents in arc lighting. Another argument was that if people had used arc lamps *in series*, and also three-wires, then there could be no subject-matter for a patent covering a system of glow lamps arranged in parallel on *the* three-wire system. We repeat we admire the ingenuity displayed in these patent cases, but would prefer to see it transferred to other fields of activity. Moreover, Diagram J D A I, had it been given credit, would, in all probability, have been deemed indefeasible in law, although

Hosted by Google

in the realm of common sense it does not seem to bear any distinct relation to Dr. JOHN HOPKINSON's Patent No. 3,576 of 1882, which it was intended to upset.

While congratulating Dr. HOPKINSON upon the substantial vindication of his claims to the invention of the three-wire system, we repeat it must not be forgotten that the decision which was given in Chancery Court III. on Saturday last seems to threaten the imposition of yet another burden upon the electricity supply business. So much ingenuity was, however, shown in endeavouring to prove that the three-wire system was neither novel nor useful, that it may be presumed those who have rendered themselves liable to a retrospective and prospective tax at the hands of a foreign corporation, will not be long before they succeed in reducing the one and evading the other. Engaged in a close competition with gas, hampered by the municipal purchase clause, confined within the four corners of Board of Trade regulations, the electricity supply business cannot certainly submit to further fines without a struggle.

REVIEWS.

Modern Mechanism. Edited by PARK BENJAMIN. (Macmillan & Co., London and New York.)

This volume appears to be based upon, or is supplementary to, Appleton's Cyclopedia of Applied Mechanics. It is arranged as a cyclopædia, and deals with American mechanism of the past ten years. The subject-matter, the authors' names, the spelling of the descriptions, and a title-page pasted in, show that the book is purely American. It contains articles on electric welding, by Prof. Elihu Thomson; on dynamos, electric transmission of power, and storage batteries, by Messrs. Martin and Wetzler; and on Niagara, by Prof. Unwin. Shorter articles on electrical subjects have been "prepared or supplied by" the following contributors: Electrical instruments, by Mr. Weston; electric motors, by Mr. F. J. Sprague and M. Nikola Tesla; the telegraph, by Mr. Edison; and electric light, by Mr. Hochhausen. The illustrations are numerous, and a large majority appear to have been reproduced with rather too much reduction from other publications.

The Standard Electrical Dictionary. By T. O'CONOR SLOANE. (London: Crosby Lockwood and Son, 1893.)

A first glance at the title of this book, and at the type with which it is printed, suggested that it was of American origin; So-called dictionaries, in reality miniature cyclopædias, are a common product of the United States. A second glance at the contents, however, suggested that it was an English work. Copious extracts from Prof. S. P. Thompson's work on the electromagnet, a Drake-Gorham steel-yard ammeter and a ring switch, Fleming's Daniell cell, Cockburn cut-out, Swinburne vacuum pump, and other instances of familiar articles are to be found, while the section on transformers is illustrated by the Ferranti and Hedgehog patterns alone. The spelling, too, is correct, with the exception of "armor" and "plow." Pursuing our quest, we found the imprint of Messrs. Hazell, Watson and Viney, London and Aylesbury. Our conclusion was that the book before us had been printed in England from American stereotypes.

As an electrical dictionary the work seems to be very good, and has no doubt been prepared expressly for the English market. We have on previous occasions admitted our inability to appreciate the use of such works, but this may be recommended to those who require them.

The Electrical Engineers' Pocket Book. Second Edition. By H. R KEMPE. (London: Crosby Lockwood and Co., 1892.)

We learn from the preface that nearly fifty new pages have been added to this pocket-book, and that they deal chiefly with dynamos, transformers, motors, tramcar systems, launches, &c. A trigonometrical table, giving degrees and quarter degrees, is provided. Neither the revision of the old matter nor the addition of the new paragraphs, accompanied though they be with the names of the authorities, incline us to alter the opinion expressed in our review of the first edition, namely, that Mr. Kempe might have compiled, and indeed might have written, an excellent telegraphist's note-book in about 160 pages, making a handy little book $\frac{3}{8}$in. thick. We doubt whether electrical engineers other than telegraphists, who, we believe, are included in the wider category, care to burden their pockets (if, indeed, pocket-books are thus carried) with instructions for fault-testing and lists of linesmen's tools, and whether the full-page diagrams of connections of dynamos are likely to be valued by anyone at all, unless he attempts to use a pocket-book as a text-book.

Munro and Jamieson's Pocket Book of Electrical Rules and Tables. Ninth edition. (London: Charles Griffin and Co., 1893.)

Among the additions to this pocket-book which are mentioned in the preface, we note that the authors are indebted to Mr. Glazebrook for Board of Trade instructions for preparing Clark cells and authorised values of the units, to Dr. Sumpner for notes on testing transformers, and to Mr. Swinburne for an article on coupling alternators in parallel. The rather formidable but well-intentioned list of symbols upon which Prof. Jamieson has bestowed so much care is to be found at the beginning of the book. We learn that they "have been submitted to a number of leading electricians of Great Britain, and have met with general approval and acceptance," but we fear that it is more easy to secure approval and acceptance than general use. If the tenth edition were printed on better paper and much larger type in the form of an ordinary book not smaller than foolscap octavo, it would form a most useful addition to the electrical text-books of the day; and that is saying a great deal.

Practical Physics. By W. F. BARRETT and W. BROWN. (London: Percival and Co.) Part I.

There are unfortunately in this country not a few physical laboratories in which a single demonstrator and an ever-vanishing professor are the sole sources of instruction to a numerous company of students. To such, and indeed to all physical laboratory classes, we most strongly recommend the handbook supplied by Prof. Barrett and his colleague. The want of a syllabus of instruction such as this is, we are sure, felt by both students, demonstrators, and professors. The practice resorted to in some large laboratories of supplying each student with written or printed directions for the experiment in hand has the demerit that it leaves the student in blank ignorance of the relation of that particular experiment to the ones which are to follow. But in many laboratories there is not even this amount of system, and the student is passed through a course of instruction which is far from being in logical order, or is left to devise experiments for himself. The present volume, which is the first of a series of three, deals with the measurement of the fundamental quantities—space, mass, and time—of force, and of the mechanical properties of matter in its three principal states. We should prefer to place Chapter VI., on the "Measurement of Force," before Chapter V., on the "Measurement of Fluid Pressure"; as we think this arrangement would be more logical, and on that account better understood by the student. With this small exception we know of no better course of practical instruction for an elementary physics class than is contained in this book. The subject-matter is arranged in short sections, each section dealing with some one experiment—first generally, then by numerical example; and a statement of the apparatus required precedes each section. Numerous small diagrams enhance the value of the book; and a collection of tables of physical constants is provided, in order that the student may verify the results of his own experiments. The introduction on matter and energy is exceedingly well written, though dealing with the subject more from the class room than from the laboratory point of view. The authors have repeated Maxwell's statement that the atoms of an element resemble "manufactured articles" in their perfect similarity. This conclusion, however, may turn out to be a hasty one; for, in the light of modern chemical research—such as that of Prof. Crookes, on yttria and other rare earths—it would seem highly probable that different groups of atoms of the same element may exhibit marked chemical differences

Domestic Electric Lighting, treated from the Consumer's Point of View. By Ed. C. de Segundo. (London: Alabaster, Gatehouse, and Co.)

Contractors as well as householders are conscious of the general ignorance which prevails concerning ordinary details of electric lighting, and shilling book after shilling book is turned out for the purpose of dispelling some of the difficulties which surround the subject. It is in the interest of contrractors and supply companies that the public should have intelligent ideas about the common domestic use of electrical energy; but every handbook that we have yet seen contains a great deal too much science and too little common sense. Intelligent ideas about gas are equally necessary, but nobody cares about knowing the percentage of olefiant gas, the weight per cubic foot of the products of combustion, or the formula for the flow through pipes. There may be a distinction between the treatment of electric lighting from the consumer's point of view, and the treatment for the consumer's benefit and convenience. Whether the author has succeeded in the former, his acknowledged object, it is difficult to say; we think he, together with all others, has failed in the latter. In discussing the use of high pressures, he makes the suggestion that "the usual high pressure adopted . . . would kill any ordinary human being." This statement without proper qualification is distinctly unfair in a book which professes to deal impartially with different systems. The author very nearly arrives at a comparison between the cost of lighting by oil and by electricity, a comparison of much more importance to many householders than a comparison with gas; but his figures are hypothetical.

Among the many random suggestions which are made "from the consumer's point of view," we find the London Hydraulic Power Company's service seriously alluded to as a source of power for domestic lighting. The Davey motor is recommended, but nothing is said about the large amount of water required for condensation, nor is anything said about the smell of petroleum engines, which appear to be recommended for ordinary town houses. The author prefers wiring an old house to a new one, and asserts that "the best time to run the wires is just before the house is to be papered and decorated," rather than while the builders are still on the premises—as if it were a common practice to clear all the builders out before the decorators began their work. An "intensity" of current of 1,000 amperes per square inch is recommended, though the author finds it difficult to see why this should have been chosen. For the encouragement, if not the invention, of this and other blessings, we must look to a well-known insurance office. "Evidently the size of the conductor should be so proportioned," says the author, "that a given per cent. drop in the furthest lamp is not exceeded." What possible use to the unhappy consumer is this ridiculous "given per cent."? If this book is not to give him the information, what *does* it pretend to give? Advice about the use of primary batteries, perhaps—we wish him joy of them. Mr. Segundo could write a much better book than this if he were to try.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

In opening the course of lectures, Prof. Unwin stated that he thought there was an advantage rather than a disadvantage in some one not particularly conversant with electricity being chosen to deliver such a series. There was a tendency now-a-days to give too much prominence to electricity, which still, however, relied in the end on boilers and engines. This undue prominence obscured the fact that there were other valuable methods of distributing power. The striking scientific success of the Frankfort-Lauffen experiment had somewhat obscured the fact that it was not intended to be examined from a financial point of view, the horse-power hour so delivered at Frankfort costing five times more than it did if generated on the spot in the ordinary way. Long-distance transmission was, indeed, not likely to be frequently useful.

* Abstract of "Howard" Lecture I.; delivered before the Society of Arts, January 13th

The origin of power-generating stations was that it paid in the long run in some cases to generate it centrally, and distribute it to individual consumers. A further reason for the establishment of central stations arose in this way: for good or for evil, population tended to gather into huge communities, in which the complex arrangement of social and industrial life led to a constantly increasing need of mechanical power for transit, for handling goods, for sanitation, and for various small industries. At first this need was met by the erection of scattered and independent motors, but this sporadic method of providing power was eminently uneconomical; especially was this the case where small motors were used, and where the work done was of an intermittent character. Then arose the question whether, by generating energy in an easily transportable form, the huge waste which went on could not be prevented. The problem was whether the economy due to concentrating the means of generating energy would pay the cost of the distributing arrangements. It was thought that just as in great towns it had become necessary to supersede private water supply with an abundant and common supply, and just as it had been found convenient to provide by municipal action for a general system of drainage, so it would probably be found convenient, and even necessary, to provide towns of a certain importance with some means of obtaining mechanical power in any desired quantity, and at a price proportional to the quantity of power used. This provided a wide field for the exercise of mechanical engineering talent, and led to many interesting developments. For the single purpose of working machinery it was found economical and remunerative, in spite of the enormous expense of laying mains in London streets, to carry out a system of supplying energy by means of sixty miles of hydraulic mains. Down to 1883 there was no system of distributing mechanical power of any kind. In 1888 there were 96 consumers taking power from the London Hydraulic Company's mains; four years later, in December of 1892, there were 1,676 consumers, and the quantity of power used had increased from a very small figure to six million gallons daily, and in no instance had the use of the power been abandoned in favour of any other system of working. A casual observer would not regard Geneva, with its 50,000 inhabitants, as the most likely centre for a great system of power distribution; yet at Geneva was the largest example of the development of power at a central station, and its sale as a merchantable commodity which had hitherto been executed. In 1871 Col. Turrettini applied to the Municipal Council for permission to place on the town mains a small pressure engine for driving the factory of the Geneva Society for the manufacture of philosophical instruments. In the event of finding that this method of working the factory succeeded, he asked the right to instal small motors in other parts of the town. Nine years later, in the year 1880, there were 111 water-motors supplied from the town mains, which were low-pressure mains, using 34 millions of cubic feet of water annually, and paying to the municipality a rental of £2,000 a year. The cost of the water was not low; it was charged at from 30 to 40 centimes per horse-power hour, or at the rate of from £46 to £48 per year. But even the high price did not prevent the use of power so easily obtainable. Since then a high-pressure system of distribution had been established, and power was now supplied more cheaply. The cost was about 0·7 of a penny per horse-power hour, or about £8 per horse-power per annum. In 1889 the annual income from water sold to factories on the low-pressure system was £2,085, and on the high-pressure system £4,500. The receipts on the high-pressure system were increasing at the rate of £850 a year. He would say a word or two on sources of mechanical energy. Wind power was used for driving ships and mills, but the intermittence of wind restricted its use to peculiar conditions. Tidal action might undoubtedly afford an enormous amount of mechanical energy; but at present the cost of embankments and machinery rendered its employment prohibitive from an economical point of view. Considered practically, there were only three sources of mechanical energy—the muscular energy of animals, the action of gravity on water falling from a higher to a lower level, and the heat derived from the combustion of fuel. By far the most important source of mechanical power was the consumption of solid fuel, chiefly in the various forms of coal. Coal was readily transportable, but the use of it was attended with certain inconveniences. Solid fuel must be burnt in an open furnace; that involved that from 20 per cent. to 30 per cent. of the heat produced by the combustion of the fuel was wasted in the chimney. Then the only easily practicable way of getting mechanical energy from solid fuel was by using steam power. Now, there was a fundamental disadvantage in transforming heat into mechanical energy by means of a steam-engine, in the fact that only about three-tenths of the original energy could by any possibility be turned into work. Next, the attendance required with an open furnace, and the difficulty of preventing smoke and of getting rid of ashes, were further disadvantages. Then there was gaseous fuel, and internal-fired gas-engines worked with a much greater temperature range than steam-engines. They had already given a thermal efficiency, as

Hosted by Google

heat machines, double that of steam-engines of large size and good type, and the efficiency of a gas-engine in transforming heat into mechanical work was enormously superior to that of a small motive-power steam-engine. On the other hand, lighting gas was more expensive than a good calorific gas. The price at which ordinary lighting gas was sold was increased by two things: first, the need of an excessively large plant to meet the excessive fluctuations in the demand for light; and secondly, by the large distributing charges, necessitated in consequence of the enormous number of small consumers. But he thought there were other gases of low illuminating power which might be produced and distributed at considerably less than half the price of London gas, and in that case, used in a gas-engine, it would compete in cost with the use of ordinary solid fuel. Sir William Siemens strongly advocated the use of cheap gas as a motive-power, and lately Mr. Thwaite had proposed a plan for employing a gas of from 10 to 12 candle luminosity through the mains of the Compressed Air Company at Birmingham. It had been shown by measurement that a gas-engine would give an effective horse-power at a total cost, including all charges, not greater than the effective horse-power derived from steam-engines. There were 2,500 gas-engines in work in London, and it was difficult to predict whether they were going to any great extent to replace steam-engines. They possessed certain disadvantages, as they were much more restricted in size than steam-engines, and worked less economically at light loads.

Prof. Forbes had called special attention to the obtaining of energy from town or ashbin refuse. Besides the sewerage which a town had to get rid of, there were large quantities of refuse which could only be got rid of by burning; the burning of refuse had been found to be less costly than any other method of disposal. Here was a fuel that cost nothing, excepting in the machinery for utilising it. Various kinds of destructors had been used, and in most of them a large quantity of the products of combustion passed away at a high temperature and carried off a considerable quantity of heat in a form in which a great part of it might be easily utilised. If any use could be found for the energy so produced, a large deduction might be made in the cost of refuse disposal. An interesting Paper upon this subject was read last September at the meeting of the British Association by Mr. Watson, who stated that with the furnace heated to a temperature of about 2,000deg. there was disengaged something like 3,550 thermal units per pound of refuse consumed. This was about 24 per cent. of the evaporative power of good coal. Taking a destructor burning six tons a day, or 560lb. an hour, they would get, utilising the heat by generating steam, 1,113lb. per hour in ordinary conditions of steam working. That was equivalent to over 50 H.P., an amount of power which was quite important enough to be valuable. It appeared that the destructors were now worked with a steam jet. From another experiment made, also by Mr. Watson, it was found that this steam jet used about 250lb. of steam per cell. In practice the results were not always so good as in some of the experiments, but Mr. Watson in one case at Leeds actually obtained 15 H.P. per cell of the destructors, and had the boiler been more efficient this would probably have run up to 22 H.P. per cell of the destructor. He (the lecturer) had no doubt that what really could be done was something between the calculated value of 33 H.P. and the real value of 22 H.P. But the chief difficulty in using power from destructors was that, while they must be worked day and night at a constant rate, the demand for power was of a fluctuating character. It was because he had at a later stage to direct their attention to a means of absorbing heat that he had given a rather detailed statement of the heat value of destructors.

Coming now to steam power used in central stations, and the competition of central stations with the use of steam power outside, he wanted first of all to make one point clear, the chief secondary cause of loss or waste of heat. In motors worked by steam, with the range of temperature available, a steam-engine might, on thermo-dynamic principles, turn into dynamical work a proportion of three-eighths, while a gas-engine might turn into work half the energy supplied by the fuel. The principal cause of waste was essentially the same in both cases, the enclosure of the working fluid in a conductor of metallic walls. The loss due to this increased with the ratio of the admission surface in cylinder to the weight of steam used. In the steam-engine, therefore, the waste due to initial condensation must increase for light loads, because more surface was exposed per pound of steam used. The evil could be diminished, but not entirely overcome by the use of steam jackets; but it is always a cause tending to make engines which are too large for their work or too lightly loaded very uneconomical. In gas-engines it is necessary, in order to prevent the destruction of the cylinder, to cool it by a water jacket. Mr. A. Witz has shown that it is due to the cooling action of the cylinder wall that part of the gas is kept below the temperature of combustion. The cylinder wall, therefore, diminishes the efficiency of the engine by preventing the full development of the gas pressure at the beginning of the stroke, and by directly abstracting heat before the stroke is complete, as in steam-engines. The evil is greater the greater the area exposed to the gas at the moment of explosion, and this is why initial compression of the expansive gas in the gas-engine is necessary to good efficiency. The gas is reduced by pressure to a smaller volume, and is exposed to a small area of cylinder wall.

One curious method of economising heat in steam-engines had been proposed in connection with central-station work at Dresden. They proposed there to generate the principal part of their power by steam-engines; but they proposed to have gas-engines also—the gas-engines being used especially during times when the load was very light—during the night, and so on. They proposed to use the exhaust from the gas-engines to superheat the steam going to the steam-engines. In that way they would get a very convenient method of obtaining superheated steam, or steam at a higher temperature than saturated steam. He had no doubt, so far as economy goes, that would work very well.

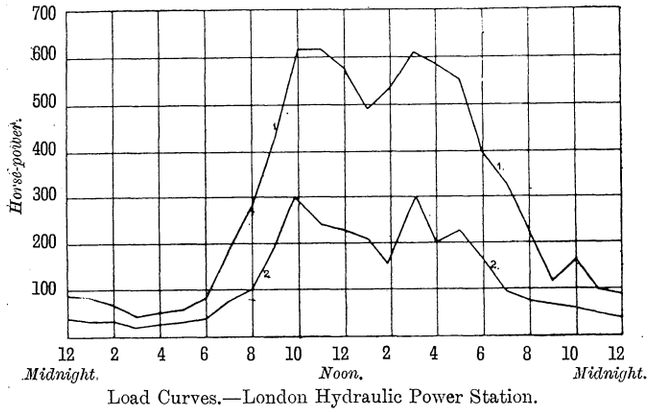
Sir Frederick Bramwell clearly indicated in 1885 that where little power was required, a steam-engine was costly for the work it did, and that where a great amount of work was required intermittently, both the engines and boilers had to work under unfavourable conditions. On the wall the lecturer had placed a table of very careful calculations of experiments on the consumption of steam and of fuel in steam-engines of very various types. It would be seen that at full load they were able to get an indicated horse power with an expenditure of 1½lb. for a condensing engine, and 1¾lb. for a non-condensing engine. It was much more difficult to get the consumption of coal by engines in ordinary daily work. What was known showed that the ordinary consumption was greater than the consumption on special experimental trials. He had found that comparatively large pumping engines of the London Hydraulic Supply Company, which worked with a fairly steady load, and which should work with 2lb. of coal per hour, used 2·7lb. on a trial of many weeks.

Where they considered electric lighting stations, where engines had to do work which fluctuated very greatly, they got results far more unfavourable. Mr. Crompton had been good enough to give figures for the Kensington station, which had excellent Willans non-condensing engines, consuming under 2lb. of coal per effective horse-power hour. These engines were in 1886 using 7½lb. per effective horse-power hour, and in 1891 3·8lb. He believed in the lowest figure mentioned they had got to about as great an economy as they were likely to get at present. These results were not isolated. Probably in very few cases were electric lighting stations working at 3½lb. per horse-power hour; in some cases the consumption was double that. In the case of small, isolated motors, far worse results than that were obtained. He had a table showing the consumption of engines in Birmingham of from 4 H.P. to 24 H.P., and these were using from 8½lb. to 36lb. per horse-power hour. It was largely with such uneconomical small engines that central stations would have to compete in supplying power; it was due to the extravagant cost of these small engines that central stations could supply power, pay the cost of distribution, and have a margin of profit.

About the cost of ordinary large electric lighting stations something more need be said. The fuel consumption in such electric lighting stations was so excessive that some very competent engineers, who forgot that their opinions were based entirely on full load trials, were disposed to throw doubt on it. He believed, however, that the figures showing a very large consumption of fuel in central electric lighting stations were quite accurate, and to a great extent they might be fully explained. First, he would call attention to the conditions under which, probably, any central power station would have to work. He had placed on the wall a number of load curves showing the amount of power used at every hour of the day. First of all, were two curves for two different dates at the Kensington Court electric light station; then there were two curves for the London Hydraulic Power Company's station; and also three curves for the Gas Light and Coke Company's supply of gas. It must be remembered that the Gas Light and Coke Company were really a central station company supplying a kind of power, and the consumption of gas varied in the way shown in the curves. A line was shown for a very fine day in 1890, another for a foggy day in 1890, and a third for a fine day in 1891. A curve, the abcissæ of which represented time, and the ordinates the rate of supply of energy, was called a load curve. These were drawn commonly for 24 hours. Apart from seasonal fluctuations of demand, the day was the natural period in the work of the central station. A load curve might be drawn for a single machine, or a single steam-engine, or for the amount of energy taken at the moment by all machines, lamps, &c., in operation in a station. The influence of fluctuation in the demand for work, on the economy of work, had long been noted and allowed for; but it was due to Mr. Crompton to say that the use of the load curve in discriminating between different stations was first indicated by him. Mr. Willans, at the

Hosted by Google

same time, showed how to determine exactly in certain cases, and approximately in all ordinary cases, the effect on economy of the fluctuation in the demand for energy due to one part, at all events, of an electric lighting station plant, namely, the steam-engine. He would point out that in the curves for the Hydraulic Power Company's station they had a tolerably steady day load; that was to say, they had a very large load, extending from something like nine o'clock in the morning to about seven in the evening. In obtaining the load factor they took the ratio of the area of one of those curves to the rectangle enclosing it, the rectangle expressing the work that would have been done if all the engines had been at work during the day. The



Load Curves.—London Hydraulic Power Station.

rectangle came out in one case as 0·17, and 0·146 in 1891. In the other case the load factor was 0·19 in November and 0·3 in December.

Let them now consider the character of the work which had to be done at a central station, work which varied enormously in intensity during the twenty-four hours; and let them see how that affected the economy of production of power by steam-engines. First, he would call their attention to a point which he thought had been a little too much overlooked. Steam engineers had generally been content to reckon steam and fuel consumption on the indicated horse-power of their engines, and not on the effective or brake horse-power. That was due to the difficulty of determining the mechanical efficiency of engines in most cases. As the

friction of the mechanism of engines was comparatively small in full-load trials, it had been tacitly assumed or allowed that this was a quantity of no great importance, and that it did not very much matter whether they reckoned the work done in indicated or in effective horse-power. Now, the electrical engineer, having very exact means of determining effective power applied to his dynamos, had very naturally and rightly reckoned his steam-engines much more by their effective horse-power than by their indicated horse-power; and the first explanation of the high fuel consumption of engines working at very varying load was that the average mechanical efficiency was lower, he thought, than had been commonly supposed. The mechanical efficiency of engines at full load was probably 0·8 to 0·85 for small engines, and might reach at least 0·9 for large engines. It was otherwise, however, when working with a diminishing load. A good many experiments made lately showed that the engine friction varied but little with the load. Mr. Willans had told him that he found his friction quite independent of the load. Now, if at full load an engine worked at 100 indicated horse-power and 85 effective horse-power, with an indicated horse-power of 50, the effective horse-power would be 35 and the efficiency only 0·7, whilst, with an indicated horse-power of 25, the effective horse-power would be only 10, and the efficiency only 0·4.

Now, to deal with another point, the influence of mode of regulation of the engines on steam consumption. In the discussion on Mr. Crompton's Paper, Mr. Willans gave a very beautiful and simple rule, which, in the case of engines running at constant speed and regulated by varying the initial pressure, gave the amount of steam used for different loads. Mr. Willans' experiments were made on a special type of engine, and did not directly throw light on steam consumption in other types of engines. Unfortunately, Mr. Willans' later experiments had not yet been published. Prof. Cotterill had been able to calculate for one large class of engine the amount of condensation that went on in the cylinder under different conditions of working. This was the case of a simple engine which had not been jacketed. He (the lecturer) had used Prof. Cotterill's calculation of the condensation to determine the steam consumption in a series of engines working from full load to light loads, and regulated in different ways. The steam consumption was very much less when the engine was regulated by varying the expansion than when it was regulated by varying the boiler pressure. Obviously, from both those considerations, from both the influence of the mechanical friction and the influence of the back pressure, the efficiency of the engine diminished when it was worked at light loads.

The consumption of fuel in central lighting stations was not to be explained by any action in the engines. Where, then, was it that this large consumption arose? It arose nearly altogether from the irregular working of the boilers, and by far the worst part of the want of good economy obtaining in central station lighting was due to the waste of heat in continually heating up the boilers and letting them cool down again. The waste created by working against a fluctuating load was a necessary and inevitable waste if they had no means of storage. The very great fluctuation of demand for current in electric lighting stations, and the enormous waste which that fluctuation caused in the working of the steam boilers and engines had compelled electrical engineers more than any other users of power to seek after means of storing energy. The gas engineer, who, like the electrical engineer, distributed power from central stations, had to meet a demand almost as variable; but he was happy in the position of having gasholders capable of storing a large quantity, sufficient usually to meet the demand for 24 hours of a good working day, and he was able to work his gas-making plant at an almost uniform rate. If they took the consumption of gas to be 25 cubic feet per horse-power hour, then the cost of gas-holders was 5s. 6d. per horse-power hour stored. The cost of gas-holder storage, reckoned on the rate of supply, not on the capacity of the gasholders, was £6 per horse-power. This made the charge for a horse-power supplied continuously through the year about 10s. What was required for electric lighting was a system of storage which would cover any possible fluctuation of supply as well as the fluctuations if gas supply were met. The electrical station engineer would be very glad to have something equivalent to the gasholder, and for a time it was thought that that something had been found in the secondary battery. But the secondary battery was limited to continuous-current systems working with comparatively low potentials, and it had two serious defects compared with gasholders. One was that the rate of discharge was limited, whilst that of the gasholder was unlimited; the other was that while the gasholder gave back all the gas it took, the battery gave back only about four-fifths of the elec rical energy it took. The most that had been done had been to use batteries capable of storing one-tenth, or in small stations one-fifth of the daily supply of energy. It might be conceded that a small battery of that kind did virtually to some extent improve the load line, and at any rate enabled the station to be worked with greater comfort, but shutting down for 24 hours was not consistent with the most economical working of the engines and boilers, and that was one of the worst faults of a variable and unpredictable demand. From data given him by Prof. Ayrton as to the yield of Epstein cells, he (the lecturer) found that with those same storage battery cells, without allowance for building, acid, or erection, the lowest cost was about £8 per horse-power hour stored, as against 5s. 6d. in the case of the gasholder, and £20 per horse-power supplied, as against £6 for gasholders.

Secondary batteries being clearly a failure as electrical substitutes for the gas-holder, was there any other means of storage available? A short time since it would have been necessary to concede that there were no other means of storage of energy suitable to the requirements of central lighting stations which would not involve an even greater cost than the secondary battery.

Hosted by Google

Mr. Druitt Halpin had worked out a method which he (Prof. Unwin) believed would play an important part in the future economics of the subject. The form in which energy was obtained in a central station was heat. Was it possible to directly store the heat? In a properly constructed holder for storing heat, with reservoirs packed together and presenting little external surface, the loss of heat might be made very small indeed. Heat to be stored must be given to some material body. Nothing could answer the purpose better than storage by heating water under pressure. Reduce the pressure and steam was generated instantly and in absolutely determinable amount, and explosively fast if reduced suddenly. The supply was given from the heated reservoir precisely as from the secondary battery, but without the same limits of rate of supply which occurred in the discharge from the secondary battery. The steam, if it were used in steam-engines, would give the supply of mechanical power which was wanted. Mr. Halpin's general idea, therefore, was this :—The heat, in the place of being used at once, was communicated to a quantity of water in boilers, and the heated water was stored until the heat was wanted. If the temperature of the water were high enough, they could get the energy back, as it was wanted, in the form of the energy of steam, and this they could get in the quantity in which, and exactly when, it was required. So much for the general idea. Now let them examine the matter quantitatively. Mr. Halpin proposed that the heat reservoirs should be under a boiler pressure of 250lb. absolute pressure per square inch when fully charged, corresponding to 265lb. atmospheric pressure. The temperature of the water would be 406deg. He proposes that his steam-engines should be worked with steam at 130lb. pressure, corresponding to a temperature of 347deg. Whenever the temperature in the heat storage reservoirs was above 347deg., they would supply steam to the engines automatically at any rate required ; 14¼lb. of heated water in the storage reservoirs would give 1lb. of steam. Suppose, to allow for radiation and steam losses, they took it that 16lb. of heated water in the storage reservoir was required to give 1lb. of steam at 130lb. pressure. A simple cylindrical reservoir, 8ft. in diameter and 30ft. long, an ordinary-sized boiler, would contain 84,000lb. of heated water. Such a reservoir of water once heated up to 406deg. would deliver 5,250lb., or 2½ tons, of steam at 130lb. pressure. The steam consumption for electrical work in good engines might be taken at 18lb. per horse-power hour in condensing, and 25lb. in non-condensing engines ; hence, one of Mr. Halpin's reservoirs would store heat enough to supply 286 effective horse-power hours for work with a condensing engine, and it would supply 210 effective horse-power hours if worked with a non-condensing engine. So much for the thermo-dynamic quantities. At present there appeared to be nothing to hinder the use of heat storage in that way. They required a boiler of no alarming size to store a quite considerable amount of thermal energy. Now, to look at the financial side of the question, one of Mr. Halpin's reservoirs, erected with appendages and with ample allowance for building, would cost on estimates he had no reason to doubt £470 ; consequently, the cost of storage, reckoned on the energy stored, would be for an effective horse-power hour £1·64, if the plant was a condensing one, as it ought to be, or £2·24 if it was a non-condensing plant. It had already been seen that the cost of gasometer storagewas 5s. 6d., and that of battery storage £8 per horse-power hour. Therefore, whilst Mr. Halpin's method cost a good deal more than gasholders, it was considerably cheaper than secondary battery storage.

LEGAL INTELLIGENCE.

Hopkinson v. St. James' and Pall Mall Electric Light Company (Limited).

On Saturday morning last Mr. JUSTICE ROMER delivered his judgment in the above action. A full report of the proceedings will be found in *The Electrician* for November 4th, 11th, and 25th, and December 2nd.

JUDGMENT.

The only point for decision in this case is whether the plaintiff's patent is valid, for if valid, infringement is not denied. The decision on this point depends upon certain questions, not of law, but of electrical science, in my opinion more suitable for the consideration of an expert in that science than of a legal tribunal. I have, however, been assisted by the evidence of skilled witnesses of the greatest distinction, and though, unfortunately, as generally happens in patent cases, the experts on the two sides do not agree, I have been enabled to come to a conclusion with regard to the objections taken to the patent, and that conclusion is that the objections fail and that the patent is valid.

In dealing with the objections I will first consider those taken to the second claim in the patent, being the claim which relates to the invention now known as the three-wire system, and which is the invention used by he defendants, and in respect of which relief is sought in this action. On this part of the case it is of the utmost importance to determine what, according to the true construction of the specification, is the invention claimed by the patentee. And to understand the specification, which is a document of necessity addressed to and framed for the consideration of the small circle of persons acquainted with the difficult subject to which it refers, the following facts should be borne in mind. At the date of the patent there were two known systems of distributing electricity for the purpose of electric lighting, to which the patent was practically directed. I am aware that, theoretically, and in its terms, the patent was not confined to the purposes of lighting, but extended to any purpose requiring the consumption of electricity in a system where the electricity is supplied at a fixed potential ; but I am satisfied that this extension is of no practical importance for the purposes of my judgment, when it is remembered that consumers of electricity generally (such as motors) can only be used with the plaintiff's invention when the electricity is supplied at a fixed potential, and I shall, accordingly, hereafter only refer specifically to lighting, though it must be understood that I intend in my subsequent observations to include the more extended purpose of the patent; and, where relevant and proper, the necessary extensions of phrase to cover such extended purposes must be taken as intended, though for the sake of brevity and clearness, I may speak only of electric lighting. The two systems I have referred to are in the evidence before me, and may properly be spoken of shortly as the parallel and the series systems. These two systems differ in principle. In the parallel system of lighting, which chiefly concerns incandescent lamps (though arc lamps may be used, but with difficulty, and not so usefully), the supply of electricity is at a fixed potential with varying current. The system derives its name from the parallel wires, which tap the main service conductor, along which the electricity flows from the dynamos, and join the other main service conductor, down which the electricity flows back to the dynamos. On these parallels the lamps are hung, and the current varies as more or less of these parallels are used for the purpose of lighting the lamps on them. In the series system, used chiefly for arc lights, the lamps are hung in series along the main conductor, and the supply of electricity is at a fixed current, while the potential varies as more or less lamps are burnt.

The first question that arises in the case before me is, whether the invention I am now considering was by the specification intended, and shown to extend to both systems, or to be restricted to the parallel system. For reasons, which I will hereafter give when examining the specification in detail, I am satisfied that the claim was confined to the parallel system. And I may now shortly state what the invention was. Before the date of the patent the parallel system was not only well known but had been much improved from its first stage, which has been called the simple parallel. In the simple parallel there was no connection between the parallels except by the main conductors, and the consequence was that, if one lighted lamp on any parallel had to be turned off, all the lamps on that parallel had also to be turned off. The improvement on this was called the compound or multiple parallel, and consisted in placing a wire, which joined the middle points of the parallels, so that on each parallel there occurred a lamp or lamps on each side of this intermediate wire. By this arrangement the lamp or lamps on one side of any parallel might be turned off, and yet leave the lamp or lamps on the other side of that parallel still burning. But even this compound parallel system had a great defect, arising from the fact that the turning off of lamps from one side only of the middle wire had the effect of increasing the brightness of the lamps remaining burning on that side and diminishing the brightness of the lamps burning on the other side. So that in practice, in a system of electric lighting, lamps kept varying in brightness from time to time as other lamps on the system were turned off or on, and this fluctuation of the lamps was a considerable drawback to the use of the system, especially in private houses. The patentee discovered the means of remedying this by a contrivance as simple as it was useful. He joined the intermediate wire to the wire connecting the two dynamos working in series, and the thing was done. For it was found (speaking shortly and not with scientific accuracy) that the difference between the electricity used on the two sides of the middle wire which caused the difference of brightness under the old compound parallel system, passed away down the central wire to the dynamos under the inventor's system, and ceased to exist as a disturbing element in the intensity of the burning lamps, and thus the brightness of the two sides was kept equalised and steady. The system so perfected, and which, as I have said, is now generally spoken of as the three-wire system, was of great practical utility, and, in lighting on a large scale, permitted the main copper conductors to be comparatively small without risk of bursting lamps, thus effecting a considerable saving in copper (which was, for practical work a great desideratum), and also a saving in the expenditure of electrical energy. The advantages of the discovery, of course, increased as more parallels and lamps were used, and were of considerable practical importance only in the case where several lamps and parallels were used, and became minimised when only two parallels were worked.

I will now examine the specification in detail in order to see that the contention on the part of the plaintiff is established, that the claim in the patent is confined to the parallel system. Now it is true that throughout the patentee does not use the term "parallel" to define the system he is dealing with. I believe this to be because he preferred to use the more appropriate scientific terms to describe the system rather than the popular term. But, in my opinion, when the specification is read with care and fairness, and well understood, it is clear that the patentee is thereby confining his claim to the parallel system. He shows throughout that he is dealing only with a system in which the potential is to be kept constant at the places where the electricity is to be supplied, and in which the current varies as more electricity is required to be used on the different wires that tap the main conductor—that is to say ; that he is dealing only with the parallel system, for on the balance of evidence it is clear that the characteristics I have named denote the parallel system and only that system. At the commencement of the specification (page 3 of the print, lines 7 to 10), where he refers in general terms to his inventions, he shows that the

Hosted by Google

system he is dealing with is one where the electro-motive force is supplied at a fixed potential. Now that is a phrase well-known to electricians (see *inter alia* evidence of Defendants Witness, Mr. Swinburne, 7th day, pages 35 and 36.) Moreover, I think that the words "such conductors" at line 9 mean "conductors for an electric supply at a fixed potential." It is possible, however, that the words may mean merely "conductors for an electric supply," and I therefore pass on, only observing that the sentences immediately following (and in particular the phrases at lines 12 to 17 and 24 to 25), appear to me to support the view I have taken as to the meaning of the words "such conductors" in line 9. Then at lines 9 and 10 and 31 to 38, the patentee describes what his invention is and its special advantages substantially, as previously pointed out by me in this judgment. At lines 9 and 31 he shows that one of the advantages is economizing the cost of the main conductors, and I may add that the very expression "main conductors" implies branch conductors which do not really exist except on the parallel system. At lines 9 to 10 he shows that this can be done "consistently with efficiency and safety," that is, as I understand it, with efficiency so as not to disturb the brilliancy of the lights, and with safety because, on this system, there was no risk of bursting the lamps by over pressure on any particular lamp. Then at lines 35 to 38 he shows that the object and effect of his third wire is to bring back to the dynamos the excess of electricity required for the lamps on the one side of the central wire, over that required for the lamps on the other side. I may now pass on to page 5, line 32, where the patentee proceeds to describe in detail the particular invention I am now considering, merely remarking, in passing, the observations at page 4, lines 44 to 53, as clearly referring to the parallel system. Now the detailed description at page 5, lines 32 to 48, when fairly read, in my opinion, shows clearly that the patentee was referring to the parallel system only—many of the expressions used as well as figure 5 being inapplicable to the series system. Then when I come to the second claim at page 7, lines 17 to 21, being his claim in respect of the invention I am now considering, I find it clearly made with reference to his detailed description at page 5, lines 32 to 48, and to Fig. 5, which, as I have before said, in my opinion, refer to the parallel system only. Moreover, in a question of this kind, depending, as it does, on what meaning electricians would attach to the technical phrases used in, and the wording of, the specification, I am entitled to take into consideration the views of the experts called as witnesses before me. With regard to this I need only say that, in my judgment, on the balance of the evidence, which is to some extent conflicting, it establishes that the specification, to an electrician, would show that the parallel system only is the one referred to by the patentee. But, indeed, on this point there is not so much so difference as might be expected, as the defendants' experts generally admit that the patentee was thinking of the parallel system, though they are not agreed with the plaintiff's experts, that he has with sufficient clearness in his specification confined his claim to that system. And some of the statements made by the defendants' experts are very significant as supporting the plaintiffs' case; as, for instance, Mr. Swinburne, seventh day, at pages 24, 25, 37, and 38.

Having come to the above conclusion as to the meaning of the specification, I now proceed to consider the objections to the claim. The utility of the invention cannot be disputed; but it is said for the defendants, first, that the invention has been anticipated; and, failing this, secondly, that having regard to the state of knowledge at the date of the patent, there was no sufficient merit, discovery, or novelty in the invention to sustain or form the proper subject of a patent. As to the first objection there are in substance three alleged anticipations relied on by the defendants—namely, those which may be shortly referred to as the Sauchiehall, the Alexandra Palace, and the Inchicore installations. A few others were referred to in the evidence, such as the installation on the steamship "City of Berlin," but these did not substantially differ from the Alexandra Palace and Inchicore cases, and need not be separately considered by me. Now, if the defendants' case as to Sauchiehall had not broken down, an anticipation would have been established. But on the whole evidence as to this, I am satisfied that there was no anticipation, and that the installation at Sauchiehall was not the plaintiff's three-wire system at all, but at most merely a case of the ordinary multiple parallel when the middle wire is not connected with the dynamos. There were two witnesses for the defendants (Andrews and Town), whose testimony, if it could have been accepted, would have established that the third wire was connected with the dynamos. Sir Horace Davey, in his summing up, referred also to a witness McKillop, but in justice to that witness I am bound to say that taking his evidence as a whole, he did not purport to say from his own knowledge that the third wire was connected with the dynamos.(See in particular his cross-examination, sixth day, at bottom of page 132). Now, as to Andrews and Town, I am sorry to be obliged to say that I cannot give credit to their testimony on the point. This Sauchiehall case broke down, and may be dismissed from further consideration. Then, as to the Alexandra Palace case that was, in my opinion, no anticipation. The following are the conclusions I came to from the evidence before me taken as a whole. This Alexandra Palace installation was not a case of the parallel system at all. It was really a mere case of two arc lamps in series with a common return between them, to the dynamos. When both lamps were burning they were burnt in series on one main conductor, and the whole electric current went along the main conductor through the two lamps, and for all practical purposes no electricity passed down the return or central wire. When one lamp only was burnt, the central wire (which was as thick as the main conductor) operated as part of the main conductor, and the electric current went along this one conductor only, through the lamp, back to the dynamos. There was no tapping, and certainly there were no parallels. There was no saving of copper in the way and of the kind effected by the plaintiff's invention. The third wire was, as I have already said, in fact, of the same thickness of copper as the main conductor, and such saving of copper as was effected was only such as is always obtained when a common return is used; that is to say, that instead of having four main conductors to burn two arc lamps separately, you have three only because of the common return. The central wire cannot be said fairly to carry away excess of electricity between lamps on one side and lamps on the other within the meaning and spirit of the plaintiff's invention and specification. For all substantial purposes the central wire either took back the whole current or none. The practical advantages of the plaintiff's invention were not, or were certainly not all, obtained in this installation. And I think it is not a fair objection to the novelty of a process which is intended to be, and which is, of great use, when applied to a system comprising many things, to say that the case of one has not been expressly excluded by the inventor, and that as the application of the process to the case of the one, so far as it could be applied to the one, was known, therefore the process has been anticipated, though the utility of the invention practically disappears when the case of the one is considered. If such an objection were allowed there could never be a valid patent for many important discoveries, as for instance many discoveries in connection with multiple telegraphy.

Then, as to the Inchicore case. That in principle is not distinguishable from, and does not go beyond, the Alexandra Palace case. The only difference is that instead of one lamp on each side of the central wire there were several lamps. But the lamps were in series—the same number on each side—and as before, either all the lamps were burnt in series on a main conductor, in which case substantially no current passed down the central wire, or one set of lamps was burnt in series, in which case the central wire became part of the main conductor, and substantially all the current flowed down it. In this case, as in the Alexandra Palace case, one of the essentials of the plaintiff's system was absent, namely, the joining of the middle points of bridges or parallels to one another. All the remarks I have made with regard to the Alexandra Palace case, in fact, apply to this, and I need not repeat them. It follows that the alleged anticipations fail.

Then, as to the second point, that there was no real invention made by the patentee. The case is put most strongly for the defendants in the following way. It is said that, taking the Inchicore case, you could easily turn the series lighting into parallel, and that to do this required no invention, and that if this were done you had the plaintiff's invention. It is also said that taking the known compound parallel system it required no invention merely to connect the third wire with the dynamos, especially as this had been done in the common return, and in the Alexandra Palace and Inchicore cases. But I think these views fallacious. No doubt now that the thing is done it is very easy to understand, and becomes obvious to all. But I do not think that it was obvious until discovered, or that it could be arrived at without thought and experiment. An electrician who knew all that had been done up to the date of this patent, and who set himself down to try and cure the known defects of the existing compound parallel system, would by no means, as of course, have hit upon the plaintiff's invention. In particular I think that it would probably never have occurred to him to regard the Alexandra Palace and Inchicore installations, which were series systems, as being likely to lead to a solution of the problem, or to try the effect of turning the Inchicore series lamps into lamps on parallel. Certainly in my opinion he could not have come to the conclusion that such an attempt would result in success without investigation and experiment, especially when it is borne in mind that the Alexandra Palace and Inchicore lamps would not have burnt in parallel. And a convincing proof that the plaintiff's discovery was not obvious lies in the fact that there were skilled electricians who at this time knew of the series and parallel systems, and some of whom had about this time to put up installations on the parallel system in which it would have been of great advantage to use the plaintiff's invention, and yet it never occurred to any of these electricians to use it, and the invention remained undiscovered by them. Take, for example, the case of defendant's witness, Mr. Crompton (5th day, page 16), who put up the Alexandra Palace installation, and of Mr. Siemens', who put up the Inchicore installation. The fact is that electricians, knowing the compound parallel system, and having the Alexandra Palace and Inchicore installations before them, were on the verge of making the plaintiff's discovery, and yet, though they were all eagerly searching for novelties and improvements, they never made it, And it is a significant fact that Prof. Silvanus Thompson (one of the defendant's witnesses) for the purposes of a lecture about this time prepared a diagram showing all the principal and newest systems or methods of lighting which were known or occurred to him, and yet it never occurred to him to suggest a system like the plaintiff's. (See Exhibit, S.P.T. 1). For these reasons I think the second objection fails, and I have thus dealt with the principal objections to the patent. But there are one or two minor points taken on behalf of the defendants with which I must now shortly deal.

It is said that the plaintiff's specification is insufficient, inasmuch as the patentee says his system is applicable to the case of alternate currents, and the defendants allege that to work dynamos in series in alternating currents they must be rigidly coupled, and that a workman is not told by the specification to rigidly couple the dynamos, and would not know that he ought to do so. Now on this point there is considerable conflict of evidence, but on the whole I am satisfied that the objection is not substantiated. I think that any workman of ordinary skill who would be employed to put up the dynamos to be used according to plaintiff's specification would know that the dynamos to be worked in series with alternating currents must keep time, and that the ordinary method of effecting this would be rigidly coupling the dynamos. The fact is that for many years prior to the patent the dynamos had been rigidly coupled in practice, and at the date of the patent it was a somewhat novel discovery, that as an exception to the general rule rigid coupling might be dispensed with when the dynamos were not in series. I need only add that a portion of Lord Kelvin's evidence on this point (third day, at page 23), relied upon by defendants' counsel, has, I think, been misunderstood. I think Lord Kelvin was there considering the case of an ordinary workman with n experience or knowledge as to dynamos. I do not think he meant to sug-

Hosted by Google

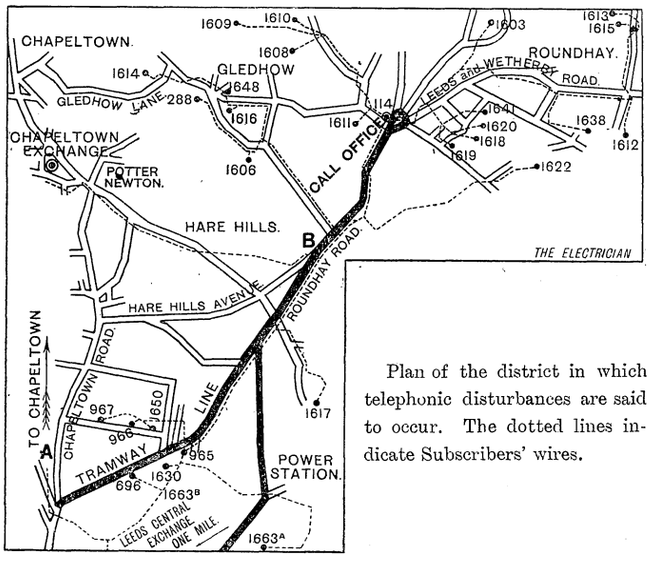
gest that a workman of ordinary skill—such a man as would naturally be employed in putting up dynamos—would have experienced any doubt or difficulty in putting up the dynamos so as to make them work efficiently in series with alternating currents. But if he did, then I think on the balance of evidence, as a whole, that he was mistaken in this part of his testimony.

The above substantially exhausts all the objections taken to the plaintiff's invention that is the subject of this action. But the defendants say the plaintiff's first claim—which concerns what I may call the potential measuring machine—is bad, and so the plaintiff's patent must altogether fail, even though the second claim by itself would be good. But the defendants have failed to satisfy me that the first claim is bad. In the first place, they say that the invention claimed is not useful. On the balance of the evidence before me I am satisfied that it is a useful invention, and can be used to advantage, though owing to a variety of circumstances it may not have been used commercially in its simple form as described in the patent up to the present time. The defendants' only other objection to this first claim is based on the allegation that the machine will not work as a practical machine with alternating currents owing to locally induced currents thereby caused. On the balance of the evidence before me I am satisfied that it will work. I think, moreover, the specimen of this machine made for the plaintiff was fairly made according to the specification, and that specimen certainly worked well. No doubt if you are perversely ungenerous enough to sit down and see how you can make a machine which, though normally in accordance with the plaintiff's invention, yet will not work, you may succeed. The model produced by defendants shows this, but that model I do not regard as fairly made in accordance with the plaintiff's invention and specification.

Having now dealt with all the objections against the plaintiff's patent urged before me, and shown that in my judgment they fail, I grant to the plaintiff the usual relief sought by him against the defendants as infringers, with costs.

The National Telephone Company (Limited) and Another v. Graff Baker.

The hearing of this action was resumed on Thursday last week before Mr. Justice Kekewich. Counsel for the Plaintiffs: Sir Richard Webster, Q.C., M.P.; Mr. C. M. Warmington, Q.C., M.P.; Mr. J. Fletcher Moulton, Q.C.; Mr. Nath. Micklem, and Mr. R. W. Wallace (instructed by Messrs. Waterhouse, Winterbotham and Harrison). Counsel for the Defendant: The Solicitor-General (Sir John Rigby, Q.C., M.P.); Mr. W. R. Bousfield, Q.C., M.P.; and Mr. Alfred Dunham (instructed by Mr. Clarance Leighton). Mr. E. Morton Daniel (instructed by Mr. F. W. Kite) held a watching brief on behalf of the Thomson-Houston International Electrical Light Company.



Plan of the district in which telephonic disturbances are said to occur. The dotted lines indicate Subscribers' wires.

The report of the Referee (Mr. Edmund Macrory, Q.C.) was read by Sir Richard Webster. The Referee stated that in accordance with the instructions of Mr. Justice Kekewich he, in company with Mr. Henry H. Cunynghame (barrister-at-law), Mr. W. H. Winterbotham (solicitor), and Mr. Swinburne, made a number of experiments on the 6th and 7th inst. at Leeds. The experiments were made both while the tramcars were running and when they were at rest. During the experiments there was a coating of snow over part of the line, which it was suggested might increase the disturbance on the telephone wires. The experiments were made at twenty-one out of the twenty-four cases of alleged disturbance mentioned in the plaintiffs' particulars. Most of these experiments were duplicated, *i.e.*, were made when the tramcars were running, and repeated when the tramcars had stopped. In the first experiments Mr. Cunynghame and Mr. Macrory, with Mr. Winterbotham and Mr. Swinburne, Mr. Leighton and Mr. Dalzell (the plaintiffs' manager at Leeds), were together at the Leeds Exchange, and telephoned to the attendant at the Roundhay call office (No. 114 on map, which we reproduce from *The Electrician* of December 23rd), and also to Sir James Kitson (No. 288). The noise of the tramcars interfered very much with hearing what was replied, and evidently interfered with the respondents hearing messages. The noise occasioned by the running of the tramcars was easy to recognise. It was a whirring sound like that made by a card when held against the teeth of a rapidly rotating cog-wheel. Sometimes it was uniform like the rushing of water from a tap, sometimes it assumed a musical note rising and falling like the sighing of the wind among the trees. It was sometimes for a short time quite silent. After having tested from the Leeds Exchange, tests were made from Chapel Town Exchange, and also from the Roundhay call office. The disturbance was such as to interfere with the hearing messages when the tramcars were running. A test was made from the telephone at Dr. Jessop's, Roundhay Mount (No. 1,603). Here, after communicating with Mr. Cunynghame at Chapel Town Exchange, and thoroughly testing the effect of the tramcars upon the telephones, both when they were running, and when they were stopped, the telephone was put through to the office of the plantiffs, Oxford-court, London, the course of the wire being from Dr. Jessop's to Chapel Town Exchange (from Roundhay call office to B on map along the defendant's line), thence to Leeds Exchange, thence through Manchester to London. This experiment was first made at 12 o'clock on Saturday, 7th inst. Mr. Winterbotham's voice was recognised in Oxford-court by Mr. Sinclair, and Mr. Sinclair's voice was recognised by Mr. Winterbotham, neither of those gentlemen being otherwise aware of the presence of the other at the respective ends of the wire. Mr. Swinburne afterwards held a long conversation on scientific matters with Mr. Sinclair. This took place while the tramcars were stopped, and Mr. Macrory listened to the conversation through a telephone-receiver switched in for the purpose. The same experiment was repeated after the tramcars recommenced running, and while the tramcar was in motion it was impossible to hear conversation, but in the intervals of stoppage the voice came out quite clearly, again becoming inaudible as the tramcar began to run. A similar experiment was made in conversing through to Blackburn, and with similar results. In conclusion, Mr. Macrory stated that his experiments enabled him to form a decided and accurate judgment, and that in his opinion the plaintiffs' telephonic system was seriously interfered with by the works of the defendant, the disturbance, in some cases being so great as to render speech entirely unintelligible. In other cases speech was to some extent audible, but an effort on the part of the listener was required to distinguish the words transmitted, and there could not be a doubt but that the effect produced by the working of the defendant's tramcars and line was such as greatly to interfere with the efficiency of the telephone by creating noise, which in all cases impaired, and in some cases entirely destroyed, the power of transmitting speech.

Mr. EDMUND MACRORY, Q.C., examined by Mr. BOUSFIELD, stated with reference to the snow that Mr. Leighton called his attention to it, and said, "I should like you to make a note in your report that there was snow on the line at the time." Mr. Leighton said, it might increase or diminish the disturbance, suggesting that it broke the contact between the wheel and the line of the tramway through which the return was made. He certainly did see coruscations of light from the make and break that was going on when the tramcar started. On the Friday there was practically no snow. On the Saturday there were several inches. The attendants of the line brushed the snow off. There was not much difference in the disturbance on the Friday and on the Saturday.

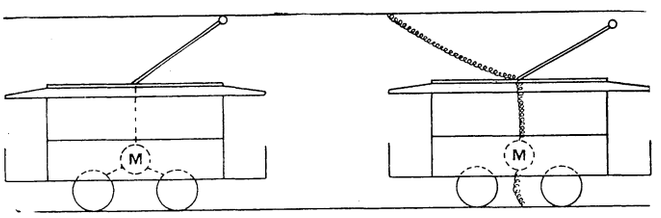
Mr. JAMES SWINBURNE, recalled, and cross-examined by Sir RICHARD WEBSTER, with reference to his previous statement that the working of the cars caused no substantial interference with the commercial utility of the telephone system, adhered to that opinion. Both on Friday and especially on Saturday last, he should certainly admit that the disturbance was very serious. He suggested the snow as an abnormal cause. Witness admitted that he had not superintended personally the installation of any tramway. The difficulty with the double overhead wire at junctions was not a question of reversal of polarity in the motor. It was a question of having a positive lead and a negative lead together, and arranging so that the trolley on the positive lead could follow its course, and the trolley on the negative lead could follow its course, without bringing the two positive and negative leads into electrical connection, and without breaking the circuit to the motor. He certainly thought that there was a difficulty in carrying the trolley over a break of two feet. Witness was then cross-examined at considerable length, as to the proper width of slot in the case of an underground conduit system of traction.

Re-examined by Mr. BOUSFIELD, witness stated that the telephone speaking itself both on Friday and Saturday, seemed much smaller in sound, except when one particular transmitter (Hunning's) was used. Then the sound at witness's end was so loud that though Mr. Macrory had a telephone at his ear and several of the other observers had telephones at their ears, witness, who had no receiver at all, could hear what was said. The effect of the snow on the contacts would be to make them bad. The difficulties he had mentioned applied to the conduit system with two conductors in it.

M. BRUNO ABDANK ABAKANOWICZ, examined by Mr. BOUSFIELD, said that he was a consulting engineer residing at St. Maur, near Paris. On May 9, 1892, he went to Leeds to inspect the defendants' tramway with Mr. Swinburne, and made certain experiments with the view of ascertaining the nature and cause of the disturbances in the telephones. The result of the experiments was that conduction played a small part in it. The disturbance caused by the cars would always be a disagreeable noise, but one could carry on conversation generally. The necessary alterations in the plaintiffs' system, in order practically to remove the disturbance would be very small ones; doubling several of the subscribers' wires, putting in a few transformers. The method of doubling back the wires and earthing them near the Exchange, if adopted in Leeds, would practically abolish electro-magnetic induction, Having regard to the length of the routes in Leeds, electrostatic effects would be of no importance. It was practical to work an exchange partly with metallic circuits and transformers, and partly without metallic circuits. It was an ordinary practice in tele-

Hosted by Google

phonic work. Witness then described an experiment made to prove that the noise on the telephone lines did not come from contact between the trolley and the overhead wire, and between the wheels of the car and the rails. (*See* diagram B. A. A. 3). He compared the noises in the telephone when the car was running without the trolley and wheel connection, with the noises there had been when the car was running with the trolley, and he could not find the slightest difference. He considered telephones upon single wire system with earth return unsatisfactory instruments. The single wire traction system was almost universal in America. Witness was then examined on the Vevey double overhead slotted tube line, which he thought could not practically be applied in Leeds for the purpose of electric traction, for the reason that the road there was so complicated. He tested the telephones at Vevey with the result that although the inductive effects were almost *nil*, the leakage was sometimes considerable, and the telephone people had been obliged to double the lines going from Montreux to Vevey. He had been to Buda-Pesth, and seen the system applied there. He did not observe any crossing of any complexity. The width of the streets at Buda-Pesth where the tramway ran was unusually great. He did not think the Buda-Pesth system applicable to Leeds.



I. II.

Diagram B.A.A. 3.—I. shews the car with the ordinary contact, the current being received through the trolley arm and discharged through the wheels. II. shews the trolley arm disconnected, and the wheels disconnected from the motor, the connection in this instance being made by means of two flexible conductors—one between the trolley wire and the positive pole of the motor, and the other between the negative pole of the motor and the rails.

After cross-examination by Mr. MOULTON, and re-examination by Mr. BOUSFIELD, Witness withdrew.

Mr. STEPHEN SELLON, examined by Mr. BOUSFIELD, said he had given a great deal of attention to tramway traction. He had carefully examined the Leeds tramways. Prior to the contract between the defendants and the corporation he was employed to negotiate with the Board of Trade with reference to the system which should be adopted. He fully explained to them that was proposed. In his opinion the Leeds tramways had been carried out in a very first-class manner, both in construction and equipment. He could confirm Mr. Abdank's evidence with regard to the experiment with reference to the effect of contact between wheels and rails, and between trolley and wire. He had visited Buda-Pesth and Northfleet. There were no complex crossings in the Buda-Pesth system. Witness was then examined on a model (S. S. 2) intended to illustrate an application of the conduit system to Boar Lane, Leeds.

Mr. BOUSFIELD: Do you yourself think that the conduit system at Buda-Pesth is one which is practically applicable to the requirements of Leeds?—If you could eliminate a great many difficulties which appear, to my view of thinking, at Buda-Pesth, it might be applicable, but, to my mind, a good many of them are not easily eliminated, and I do not see how they would be at the present moment.

WITNESS was then examined in detail as to the possibility of working on the Buda-Pesth system, but with a ¾-inch slot instead of a 1-inch slot. In his opinion the result of reducing the dimensions of the slot would materially increase the friction, and would tend to wear away the collector much quicker. He did not think the Northfleet system presented a way out of the difficulty. He had always looked upon the application of the series system at Northfleet as a failure of mechanical working. It failed while he was there each time. The failure was due to the spring-jacks being knocked down by the plough and the contact disabled. The Blackpool system was one of two conductors of the same polarity, the return being by the rail. It would affect the telephones of the neighbourhood. As to the Birmingham battery cars, up to now they had not been a commercial success, the cause being the deterioration of the battery. He had visited the installation, and knew most of the officials in connection with it, and he had also got the report of the Birmingham Central Tramway Company.

Mr. JUSTICE KEKEWICH: We want to know what you yourself have seen, not what somebody has reported.

WITNESS: What I have, in my opinion, to prove the point, is the Directors' Report.

Mr. JUSTICE KEKEWICH: I do not want the Directors' Report; for aught I know (I do not want to suggest that it is so), it may be a cooked up report in order to declare a false dividend. What do I know of it?

Mr. BOUSFIELD: My friend's plan of Buda-Pesth may be cooked up perhaps, but we have not suggested such a thing. One could not conduct a case if one objected to such things.

Mr. JUSTICE KEKEWICH: You certainly could not conduct a case if you put in Directors' Reports as accepted statements of facts.

Mr. BOUSFIELD: I will not press the matter after your Lordship's expression of opinion.

WITNESS, in continuation, stated that he knew for a fact that they had been using E. C. C. cells in Birmingham; they had now discarded them, and were trying Epstein cells.

Cross-examined by Sir R. WEBSTER, Witness said it was very possible that when asked questions in 1890, as engineer to the Wellingborough Tramroad Bill, he protested against answering electrical questions on the ground that he was not an electrical engineer. He made his plan of Buda-Pesth in August, 1892. He made it for the purpose of his own information as to what the electrical tramway at Buda-Pesth was. He did not make it for the purpose of showing electrical connections. It was probably necessary that there should be certain junctions to get the trams on to the lines at all. In Blackpool, his idea as to the success of the reduction of the slot was that it was due entirely to the fact that they were able to have two conductors, one on each side of the conduit. If they had not had two conductors he thought they would have had great difficulty in even getting an electrical connection. As a general tramway engineer he had been consulted about the Thomson-Houston system. There was an interference with the telephone at Leeds, but not in such a way as to put a stop to conversation.

Re-examined by Mr. BOUSFIELD, Witness said he was not an electrician, but he did not think it involved much acquaintance with electrical principles to understand how the cars were driven by a current of electricity supplied by a dynamo to wires outside, but he should not like to be cross-examined on electro-static induction.

Mr. ROBERT WINTHROP BLACKWELL, examined by Mr. BOUSFIELD, stated that he was engaged in business in London as an electrical engineer. He had been General Manager and President of the Bentley Knight Electrical Railway in New York. In 1883 he had constructed a short trial line of 200 yards in length in Cleveland, Ohio, on the series conduit system. In 1885 he built in Providence a short test line with double conductors in an iron conduit. In 1886 he constructed a line at Woonsocket, about two miles in length, using two double overhead conductors. It might fairly be said that the only practical commercial system that remained to-day was the single overhead conductor system. He should regard the working of any complication on anything but a single trolley wire system as hopelessly impossible, commercially; that was to say, it would be accompanied by so many troubles that the switches could not be maintained with anything like satisfaction to the public, the keeping of the conduits clean and properly drained out was an extreme difficulty; for instance, in an enormous conduit of three or four miles, he had to keep a man for each length of a mile merely cleaning out. The width of slot in America which used to be used was ⅜ to ⅞; that was the usual slot to begin with, but it invariably reached an inch, and at places where curves occurred they took as much more as they could get without being interfered with by the powers. Of course, the slots used in the old days were arranged so that they could be widened at will. In Boston a waggon wheel was caught in the slot and the team ran away. He had to buy the team and waggon. In all the conduit lines he had spoken about it was necessary to have special police to keep the boys off; and for at least a month or so after the opening of each line it was a constant struggle to keep it in operation at all, solely on account of interference by the boys He worked for, practically, a year or a year and a-half, on the question of getting a switch which could be used for double overhead conductors, and having failed, eventually took up all switches on the line, and gave up their construction, so than whenever two cars met, the drivers of the cars exchanged trolleys, rather than turn the cars. That was a most clumsy contrivance, involving stoppage of both cars, but they found the switch to be useless. The Vevey system was utterly impossible for Leeds.

Cross-examined by Sir RICHARD WEBSTER, Witness stated that he was retained in the interest of electric traction by certain firms in England who were constructing under his advice. The Thomson-Houston Company was an antagonist of his and practically drove him to the wall in 1890. He never examined the Leeds system, with an eye to the present suit. Taking the Leeds tramway as it existed, he did not suggest there was any difficulty whatever in establishing it on the double overhead wire system, though he should not be willing to estimate the added expense. If they submited to any expense, there was also no difficulty whatever in working the Leeds line on the conduit system.

Mr. CLARANCE FRANK LEIGHTON, examined by Mr. BOUSFIELD, stated that he went to Stockholm and investigated the telephone system. There were two exchanges. There was the Government Exchange and the Exchange of the Almanar Company, with between 8,000 and 9,000 subscribers. The wires all ran to a central tower. They were in course of changing from earth-returns to metallic returns. When he was there they had changed rather more than 2,000 of the earth-returns to metallic returns. He went outside the Exchange and examined the method of stringing the wires upon the poles in different parts; they crossed the metallic circuit wires once in every five poles. He spoke on the telephone to various subscribers. The Government Exhange was entirely metallic. It had about 1,200 subscribers. The Government insisted on the Almanar Company changing their wires to metallic circuits. As things were, partly with earth returns, and the Government Exchange having metallic returns, the subscribers intercommunicated. The metallic return was taken to earth at the Exchange.

Mr. MOULTON: I do not want to ask anything.

Mr. JUSTICE KEKEWICH: How many more witnesses have you?

Mr. BOUSFIELD: I have Prof. Forbes and Prof. Silvanus Thompson.

The Court adjourned.

FRIDAY, JANUARY 13TH.

On the hearing of the case being resumed, Mr. BOUSFIELD stated that Prof. Forbes was ill, and would not be able to attend and give evidence.

Mr. JOHN SERJEANT WISE, examined by Mr. BOUSFIELD, said he was an American lawyer, and had made a special study of the question

Hosted by Google

of disturbances between telephones and tramways. Witness lived in Richmond, Virginia, where a disturbance arose between the telephone and the electrical railway. The matter was entirely set right by the adoption of the Maclure or "trunk return" system of telephony. Witness gave evidence as to growth of the metallic circuit system of telephony in the States, and as to American electric street railways. The Madison Avenue cars, on the Julian system, ran by his door every day. They came out generally with a storage battery, and went back with a mule. To-day the twelve cars of that system were "banked," and for sale. There was no doubt of the fact that up to the present time, according to the intelligence and experience of American electricians and engineers and tramway men, the single trolley was the only system that had been developed as a success commercially and mechanically and electrically.

Prof. SILVANUS PHILLIPS THOMPSON, examined by Mr. BOUSFIELD, stated that he had had experience of the plaintiffs' telephone system in London. At the time when he was a subscriber, the disturbances were so great that he ceased to be a subscriber. He could never make himself heard. It was simply useless to him. He had talked more recently over a London Exchange from various points in London, and the communication to-day was certainly better than it was He had long held that the only rational way to lay out any telephone system in any town or city, not to speak of scattered districts, was to give every subscriber a metallic circuit back to the exchange.

Sir RICHARD WEBSTER : You have been demonstrator and lecturer, and have had very considerable electrical experience now for a great many years, and have written books on the subject, and endeavoured to teach people, as much as you could, what you yourself knew ?—Yes.

You have been, I must not say a disciple, because you are perhaps more entitled to be priest, you are another apostle who has advocated the return wire ?—Consistently, for a great many years, I have advocated the use of the return wire for telephonic purposes.

People are very deaf still ?—Some people are.

And I am afraid the majority ?—Oh, no ; the majority are very fast converting their lines.

Witness was then cross-examined at length as to the efficacy or otherwise of doubling telephone wires past disturbing circuits ; the relative strengths of telegraph, electric light, and electric traction currents ; the use of condensers and transformers on telephone circuits.

Mr. OSCAR TERRY CROSBY, examined by Mr. DUNHAM, said that he resided at Boston (U.S.A.), and was vice-president of the American Institute of Electrical Engineers, and had been an officer in the Engineer Corps of the United States Army. He was now the general manager of the railway and power transmission departments of the General Electric Company. It had been the fate of the double-trolley installations to be supplanted by the single-trolley system. The double-trolley system had ceased to be used because it was more difficult to instal originally, on account of the greater number of parts that had to be used, and because it was found exceedingly unreliable in its daily operation.

Mr. JOHN CHARLES CHALMERS, examined by Mr. BOUSFIELD, said that he happened to read Lord Kelvin's evidence about the electric lighting of the tunnel trains near Glasgow, and the consequent telephone disturbance. He had had to do with the four telephones affect d by that particular disturbance. He doubled the wires back for a considerable distance, and earthed them some distance from the line of electric disturbance. It was almost a perfect cure.

Cross-examined by Sir RICHARD WEBSTER, Witness stated that he had not read Mr. Sinclair's evidence in this matter nor that of Mr. Dalzell. They were all private wires, and did not go to the exchange at all.

This concluded the case for the defendants.

Mr. JUSTICE KEKEWICH said that, broadly speaking, there were three questions before the Court : first, whether the telephonic system of the plaintiffs was to any material extent disturbed by the operations of the defendants ; secondly, whether the plaintiffs could themselves, by adopting a system different reduce it to a negligible quantity ; and, thirdly, whether, assuming that there was a disturbance, the defendants were relieved from the ordinary obligation of British subjects of so conducting their operations as not to interfere with their neighbours. As regards the first, he was satisfied, from the evidence, and particularly from Mr. Macrory's report, that there was a material disturbance. As regards the second question, he had yet to be persuaded that it arose at all. If his view were correct, the result was that the body of evidence adduced by the defendants, to show that the plaintiffs by adopting an entirely new system might avoid interference, was no answer to their claim. The third question was a momentous one, and to his mind had been all along and still was, the only real question in the case, namely, whether the defendants were entitled to do that which they were doing, admitting for the purpose of argument that it was a serious interference with the plaintiff company's works.

The SOLICITOR-GENERAL, in reviewing the evidence, said the case was one of nuisance, not depending, so far as the plaintiffs were concerned, upon statute law at all. They came forward to claim a common law right. What was a common law right ? It was a right to be protected from a nuisance. What was a nuisance ? A nuisance was an interference with an easement, or an interference with real property, but involving the possession of that property. The mention of the dates would satisfy his Lordship that there could be no easement. Telephonic communication was not known in England, at any rate, 20 years ago ; there could not be anything in the nature therefore of immemorial usage, there could be nothing in the nature of an enjoyment which would by prescription give rights against any person at all. They had had cases in which attempts were made to have, for instance, the current of air to a windmill, to have the current of air to drying grounds, to have the right to water, not flowing in a defined channel, to have all these things protected on the ground of ancient user, or of user throughout a sufficient length of time. The only negative easement in any way dealt with by the Prescription Act was the negative easement of light, which, founded originally on the idea of Grant, now had a statutory foundation, and became an indisputable right after the lapse of 20 years' user. What was there in the present case in the nature of interference with any right of property other than an easement ? What was there in the way of interference with the rights of real property, or any property possessed by the plaintiffs, or any of them that could come under the definition of a legal nuisance ? Let them consider the case of two adjoining landlords, owners in fee, who possessed large estates, on one of which it was begun to carry on the business of sending messages by telephone without any right derived from statute to do this, but doing it simply in the capacity of landowner, and side by side, the owner of the other estate, equally without in any way invoking Parliamentary authority, desired to use his land by running for his own purposes a tramway upon it. He submitted to his Lordship that in such a case the fact that the one owner, the plaintiff, had established on his own land a system of telephonic communication would not in the slightest degree interfere with the right of the neighbouring owner to establish on his land a system of electric traction, although it might materially and substantially interfere. A man was not to be treated as the owner of property in the sense that there could be allowed no kind of interference with it. Over and over again it had been laid down that he must only claim to use his property in one of the ways known to the Common Law. If that were so, the case was really at an end. Unquestionably from the time when Leeds had been a town, and from all the ages before that under which the earth was subject to the same physical conditions, there had been electrical disturbances propagated from one piece of land to another in a way that even yet was not understood. There was no right of property in these electrical phenomena. Perhaps of all others the closest analogy was that of underground water. The earth was a reservoir of underground water, and a man had a perfect right to sink a well upon his own land and to draw to himself by that means not only the water which originally at the time of sinking the well was upon his own property or came there in the natural course of things without his assistance, but to draw from neighbouring properties whatever water they had, provided only that was done by simply getting into his well the water that percolated through in a natural way. So far as they knew, the earth might be treated as a common reservoir of electricity. With regard to this Telephonic Company, assuming them to be the owners of every inch of land over which their wires went, upon which their poles stood, what right did they get by the expenditure of money on their installation to interfere with the operations of a neighbouring landowner ? The case of the well appeared to him to be for this purpose exactly parallel. When did the exclusive right arise ? Was it the first man who spent the money who controlled the other ? If so, the right of the Telephone Company was perfect before ever they transmitted in the way of commerce a single message. Was that in accordance with the Common Law idea ? It was only when they came to instruments of great delicacy that anyone could tell that there was interference. But could it be said that the use of a delicate instrument on one's land was in any way to interfere with the *primâ facie* rights of a defendant on his land ? It was now established that to a great extent nuisance must be determined by the surroundings, that was to say, that one could not have in a business quarter where there were factories, making a noise with steam hammers, and so on, the same degree of quiet or the same enjoyment of property as one would have in a country place. What did that involve ? It involved that the question of nuisance was to be tried more or less on the balance of what was reasonable and fair. But the plaintiffs in the case had a very different position from that of the landowner that he had imagined hitherto as plaintiff exercising the fee simple over the property. It had not been attempted to be made out, nor could it, of course, be that the Leeds system of telephones was in any one instance carried out from end to end with any wire on the property of the plaintiffs. They carried, not because they had any right to do it, but because no one had interfered with them, not because they had any Parliamentary right or any right by way of grant, to carry their wires from their Exchange to different parts of Leeds. Therefore, they were in a totally different position from plaintiffs who had the fee simple of all the land intervening between the Exchange and a subscriber's house. They made use of property which was not theirs at all, simply because no one had interfered with them. A right of that kind was a right in the sense that no one objected—there was no harm done—but how could it be the basis for an action of nuisance ? In the actual case sensitive feelers, such as never existed until the last twenty years, were set up, which placed the Telephone Company in a novel relation to all owners of land in the neighbourhood. There were numerous cases that had been decided in America, which, in so far as they depended upon the same principles as English Common Law, might be illustrative and useful. But what made those cases of less importance was, that the plaintiffs, though they were uniformly defeated, yet came forward in a totally different and in a much more advantageous position than the plaintiffs in the present case. In America it was always a conflict between two charterers. So far as he knew, the case now before his Lordship was the first case in which any telephone company had set up such a claim as was here set up at Common Law. Never had it been suggested before, so far as he knew, that at Common Law a claim like this could be supported. His Lordship knew well that here there was nothing but the Common Law remedy. There was no charter, no statutory power, all that existed was that the Postmaster-General, as representing the Crown, had a monopoly of telegraphic communication. Telephonic communication was telegraphic communication, and it would be an infringement of the Postmaster-General's monopoly, if the business of telephonic communication were carried on without his license. In the present case they had his license which preserved them from attack on the part of the Crown, but it gave no authority as against anyone else. They were simply trade adventurers, carrying on a business in so far as they were permitted to do so, but without any shadow of legislative authority at all. He had heard it said that in the Observatory at Greenwich the Astronomer-Royal was interfered

Hosted by Google

with in some of his nice observations and experiments by persons exercising the ordinary rights of property at a considerable distance from him. Had it ever been thought that by reason of the delicacy of the instruments, even by reason of their national importance, or on any ground at all, there was any right to restrain them in the ordinary use of property which did not amount under ordinary circumstances to a nuisance? The learned counsel then dealt at length with previous judgments in analogous cases (*Reinhardt* v. *Mentasti*, 44, Chancery Division, page 685; *Bamford* v. *Turnley*, *Gaunt* v. *Fynney*, *Robinson* v. *Kilvert*, 41, Chancery Division, page 88.) With regard to the sending of ordinary telegraphic messages, the interference with that would not have been a nuisance; therefore, properly the Postmaster-General had got inserted into the Provisional Orders a condition that his clients should not interfere with him. Then they did not interfere with him. They had had one of the principal officers of the Post Office in the box. It was only because this business of the telephone was a hundred or a thousand times more delicate than even the delicate operation of telegraphy that any question arose upon it. The learned counsel then proceeded to quote from judgments in the United States Courts bearing on the case (*Railway Company* v. *Telegraph Association*, Ohio *State Reports*, Vol. 48, page 390).

The Court then adjourned.

TUESDAY, JANUARY 17TH.

On the hearing of the case being resumed, Mr. BOUSFIELD stated that the Solicitor-General was unable to resume his argument. Mr. Bousfield then continued the argument adducing further judgments bearing on the action. After Sir Richard Webster, Mr. JUSTICE KEKEWICH announced that he would give judgment as soon as his other duties permitted.

A full report of the proceedings will appear in our next issue.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 30, 1892.

The Underground Rapid Transit Franchise.—The Rapid Transit Franchise was offered for sale at the New York City Hall yesterday noon. A number of city officials, together with prominent street railway men, were present, and great interest was manifested in the result of the sale. When the secretary of the Rapid Transit Commission asked for bids there was no response for some little time, when finally Mr. W. Noland Amory, of New York City, offered $500 for the franchise and one-half of 1 per cent. per annum on the gross receipts, which he estimated at $50,000 per year. No other bids were received, but Mr. Amory made a second bid of $1,000, and paid the commissioners a $100 deposit on that amount. If his bid was accepted he was prepared, he stated, to deposit $1,000,000 in five days, but he would not name his backers. The Rapid Transit Commissioners took these bids into consideration, but promptly passed a resolution refusing to accept them, on the ground that they were not advantageous to the public and the City of New York. The Commissioners were greatly disappointed that no other bids were received, and it is generally considered that the underground system which has been so carefully worked out by them, will not be constructed. The Commissioners now will probably be compelled to devise some rapid-transit scheme by means of elevated structures, which will not involve so large an outlay of capital, and will prove a more profitable investment.

Electric Traction in New York.—The Board of Aldermen has granted the Union Railway Company a franchise to extend its lines south of the Harlem River, and to use the trolley system. This will be the first trolley road in New York City south of the Harlem River, and the granting of the franchise has caused considerable comment, as public opinion seems to be against the introduction of this system into the city, and most of the large dailies take every occasion to denounce the trolley in the strongest possible terms.

The West End Street Railway.—The large new car stables of the West End Street Railway at Everett, Mass., were destroyed by fire on the night of December 24th, resulting in the death of four *employés* and a loss which is estimated at $135,000. The fire, according to the testimony of the engineer in the boiler room, was caused by a sudden back draught as he threw the furnace doors open. The flames spread quickly, and the men in the building had barely time to escape; a few of them rushed back in order to save some of the property, but four of them were killed in consequence of the act. The building was of wood 80ft. wide, 283ft. long, and 38ft. in height, and had been constructed for the purpose of storing electric cars.

The Milwaukee Street Railway Company.—The plant of this Company was destroyed by fire on the morning of December 28th, and the loss is estimated at over $500,000. A bomb was thrown into the main building causing a tremendous explosion, and in a few minutes the structure was in flames. In the car shed there were fifty new electric cars, and nearly all of the summer cars owned by the Company. The machine shops were built during the past season, and fitted with the finest machinery. Every effort is being made to capture the incendiary, and a large reward is offered. This is one of a series of fires which began on October 29th, and which has now resulted in a loss of nearly $2,000,000 worth of property.

The Edison Lamp Litigation.—The general counsel for the Edison Electric Light Company filed a Bill in the United States Circuit Court last week asking for an injunction to restrain the Westinghouse Electrical and Manufacturing Company from manufacturing and selling incandescent lamps that infringed the Edison patents. The Bill alleged that since the injunction granted by the United States Circuit Court of Appeals the manufacture of these lamps had merely been transferred from the shops of the Company restrained to those of the Westinghouse Company. The Court granted an injunction with provisions similar to those which had already been granted by the Court of Appeals.

NEW YORK, *Jan.* 7, 1893.

The Westinghouse Lamp.—The new Westinghouse lamp has not yet materialised. As your readers have been kept informed regarding the expectations of the American public, they will remember that the lamp was at first promised for December 1, 1892, it being necessary at that time, just after the decision in the lamp suit had been rendered, to give the public to understand that the adverse decision would in no way affect the Westinghouse lamp business. A little later, however, it was learned that the lamp would not be placed upon the market until January 1st, and the retail prices were announced. So that it was assumed that all the processes of manufacture had been arranged in detail, and that the Westinghouse stock-room was rapidly filling up with the new lamps. The latest announcement, which has been something of a surprise to the expectant public, is to the effect that the new lamp contains an attenuated nitrogen gas, and that it will be placed upon the market "early in January." There can be no question that this latest announcement has made the public rather sceptical, and those acquainted with the situation, as well as the general public, are beginning to wonder what all this delay and change of base on the part of the Westinghouse Company means. Very much adverse criticism has been stirred up by the announcement that the Company has seen fit to trot out the old idea of a nitrogen lamp. It is, however, pointed out by some that the announcement specifically states that the atmosphere within the lamp is "attenuated," and that probably the very smallest possible quantity of nitrogen is used, so that the Company avoids the possibility of being cornered by the General Electric Company for using a vacuum lamp. The periodical rumours concerning the consolidation of the Westinghouse and General Electric Companies have again been given wide circulation, but have been as promptly denied by nearly all parties concerned. There are some, however, who still insist that a consolidation will take place, and that in the near future, and also insist that the dilatory policy of the Westinghouse Company in bringing out this new lamp is a part of the game which it is necessary to play in order to secure the consolidation on desirable terms.

Electric Motors in Machine Shops.—The application of motors to tools is receiving considerable attention among practical engineers in this country. A number of inventors are at work designing motors which are compact, dust-proof, and self-regulating, adapted to direct attachment for the operation of lathes, drill presses, shop saws, planers, and other machine shop tools. There can be no question that

Hosted by Google

motors of this kind will, if adapted to the standard tools now in use, find very wide application, and will become immensely popular. It is expected that the numerous plants of this kind that will be in operation at the World's Fair will give a more widespread circulation to the possibilities and capabilities of this application of the electric motor than could otherwise be obtained, and for that reason it is thought that the business in this line during the next two years will be placed very substantially upon its feet.

CORRESPONDENCE.

A DIFFERENTIAL WATTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In accordance with your invitation, I send you some comments on Mr. Kennelly's differential wattmeter, described in last week's *Electrician*.

So much interest in the subject of dynamometer wattmeters for measuring power in alternating-current circuits has been raised by Dr. Fleming's Paper on "Experimental Researches on Alternate-Current Transformers," recently read before the Institute of Electrical Engineers, that the experience of others in the production of a satisfactory instrument is, at present, particularly valuable. In choosing the differential principle Mr. Kennelly has doubtless taken a step in the right direction, and if the inconveniences attending his arrangement can be sufficiently minimised, we may expect the differential wattmeter to be the wattmeter of the future. A further development we may hope to see carried out, is a combination of the differential principle with Dr. Sumpner's method of testing transformers, described in *The Electrician*, July 1, 1892, in which only the power wasted in the transformer leads and testing apparatus is abstracted from the mains.

Mr. Kennelly's instrument will be very valuable for the tests for which it was designed; but one would expect trouble in using it, for making zero adjustment is apt to give the suspended parts a pendulous motion, especially where long suspensions are used. The period of this instrument would also be rather great, being not less than 6 seconds or probably nearer 10 seconds.

The chief disadvantage, however, is the necessity of using auxiliary coils to balance the residual induction of U and *l*, or L and *u*, respectively. By proper relative adjustment of the coils on the instrument and their connections these auxiliaries could be dispensed with, provided the shaft which connects the upper and lower suspended coils is sufficiently rigid to prevent appreciable twist; for although the suspending wire is only subjected to the difference of the two torques due to the two dynamometers, the connecting piece takes the full torque of the lower pair of coils. In the case mentioned in § 4 (of paper) the latter is about 30 times the former. Disturbance by leads might have been lessened by using larger numbers of turns in the fixed coils. It is also important to arrange the thin flexible wires which lead the currents to and from the swinging coils so that they exert no resultant deflecting moment on those coils.

In alternating current wattmeters (especially differential ones) the presence of metal in the form of cases, terminals, &c., is highly objectionable on account of eddy currents generated therein affecting the swinging coils, and the multitude of binding posts near the coils may prove a source of error. For the same reason, the shaft which connects the two swinging coils should not be of metal.

The four sets of windings in each dynamometer give the instrument a very wide range, but the statement in § 7 that it can be used for any transformer of ordinary type up to 100 kilowatts seems very doubtful. Even if the secondary pressure be 100 volts the current will be 1,000 amperes, and this gives a current density of 80,000 amperes per square inch even if the thickest coil be used. The instrument would therefore be burnt up if left on for a short time.

The table of resistances, inductances, &c., of the several coils would be very valuable if they could be trusted, but they do not seem to be very reliable. For example, U 3 has 28 turns of No. 15 wire, resistance 0·0388, inductance 0·055, ∴ time-constant, *i.e.*, *inductance* resistance, 0·00142; whilst L2 has the same number of thicker wire, viz., No. 13, but its resistance is given as 0·22 and inductance 0·052, which gives a time-constant of 0·00024. Apparently the resistance is wrong; probably it should be 0·022. But even if this correction be made the other numbers are not very accordant.

It would have been interesting if the construction of the non-inductive resistances put in series with the pressure coils had been described in detail, for on this the accuracy of the instrument mainly depends. With a 20,000 ohm coil in series with a swinging coil whose inductance is 6·6 millihenrys one is hardly likely to get an error due to lag (see end of § 10). It is error due to lead that is more likely to occur, owing to the capacity of the non-inductive resistance more than overbalancing the inductance of the swinging coil. To prevent this the resistance would need to be made in a special way.—Yours, &c.,

T. MATHER.

THE PRICE OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been much interested in your recent correspondence on methods of charging, and as the problem of profitable electrical supply so widely differs from that of water or gas, it is not surprising that the existing legislative methods of charging leave much to be desired. The adaption of electrical energy to lighting, cooking, heating, and motive-power has so much to recommend it from the sanitary point of view that it is rather surprising no suggestion has been made to introduce an Act making its use compulsory, and to levy a rate on all householders, based on the rateable value of the premises. This would probably introduce a welcome change in the condition of life: for even the hairdresser would derive benefit, as bald heads would no longer be caused by the fumes and noxious vapours of gas; the doctor's bills could be paid by postal orders or stamps instead of heavy cheques; the coal merchant would have to take down his mystic announcements of "selected cobbles," "Silkstone," and "Wallsend;" and the decorator could devote more time to art, as whitewash and arsenical wall papers could be replaced by silk or other drapery. In the absence of such a healthy legislation other means have to be devised for allowing the enlightened user to show his appreciation of the benefits received by charging him at a rate per unit, and registering his consumption by a meter which attains an integrity unknown to the gas Ananias. It is clear that this rate per unit ought in some way to be adjusted according to the quantitative and qualitative consumption of each customer, and your columns show many ingenious suggestions to attain this end; but I venture to think that in your travels from Brighton to Manchester, throwing in the Scott meter and Kennedy maximum indicator, you have had a smooth journey along a road clear of obstacles which will appear in practice. The adjustable meter you describe in your issue of December 16th has much to recommend it, and the points adduced in its favour appear too modest, for a slight addition to the mechanism would create a new diversion in the household, and enable economy to be studied. I allude to the possibility of attaching a bell or gong, arranged so as to strike when the actuating magnet is excited from the station. In careful households the result would be interesting, for the cook would rush upstairs to her mistress, "Please, mum, the meter's struck nine times the last half-hour, and that means fourpence a unit; may I turn on the kitchen fire?" Of course, this refers to a progressive household which has ceased to destroy coal in order to heat the chimney and make ash in the grate; but servants still speak of the electrical heater as "the fire." The responsibilities of the Central Station superintendent would certainly be increased by the adoption of this meter, for the mysteries of the kitchen and general illumination would only be practised during the periods of meter retardation, and the station revenue would

ELECTRIC LIGHT & POWER COMPANY
(LIMITED),
CONTRACTORS FOR CENTRAL STATIONS
FOR TOWN LIGHTING.
MANUFACTURERS OF
DYNAMOS, ALTERNATORS, MOTORS,
TRANSFORMERS, SWITCHBOARDS,
AND ALL REQUISITES FOR ELECTRIC LIGHTING.
BATTERSEA FOUNDRY, LONDON, S.W.

E. S. HINDLEY,
ENGINEER.
London Show Rooms and Stores— 11, QUEEN VICTORIA ST., E.C.
Works— BOURTON, DORSET.
STEAM ENGINES
HORIZONTAL, VERTICAL, PORTABLE AND FIXED.
SPECIALLY SUITABLE FOR
ELECTRIC LIGHTING PURPOSES.
ECONOMICAL TO USE. MODERATE IN PRICE.
These Engines are controlled by E. S. HINDLEY'S new Governor, which maintains a perfectly uniform speed under sudden variations of work, and is adjustable when working.
Also
STEAM ENGINES for all PURPOSES.
SAW BENCHES, PUMPS,
SHAFTING, PULLEYS, &c.
Illustrated Catalogues, Photos, and detailed Information free on application.

INSULATORS
Of All Descriptions, combining the Greatest Strength with Highest Possible Insulation, in Bristol Glazed Stoneware and Special Porcelain Stoneware (White).
ALSO BATTERY JARS, PRIMARY AND SECONDARY, AND POROUS CELLS.
PRICE, SONS & COMPY., The Potteries, BRISTOL.
LONDON AGENCY: CHAS. D. BARKER, 113, MIDLAND ROAD, ST. PANCRAS, N.W.

CHEMICALS
ALL KINDS for ELECTRICAL WORK, and also for INDIA-RUBBER & GUTTA-PERCHA MANUFACTURERS,
SOLID SULPHURIC ACID and BICHROMATE SALT for EXPORT.
G. BOOR & CO., 1 & 2, Artillery Lane, Bishopsgate, LONDON, E.C.
CONTRACTORS TO THE POST OFFICE, WAR OFFICE, ADMIRALTY, INDIA AND NEW ZEALAND OFFICES, AND LEADING TELEGRAPH COMPANIES.

ADDRESSES.

LAING, WHARTON, & DOWN, 82a, NEW BOND STREET, LONDON, W., Electric Light Engineers & Contractors. Manufacturers and Suppliers of every requisite for Arc or Incandescent Lighting, Dynamos, Lamps, Switches, Electroliers, Brackets, &c. Specialities in Primary Batteries for Electric Lighting, Venetian Shades and Glass, Carbons, &c. Temporary lighting on any scale at short notice. Estimates free. Telephone No. 3602.

JULIUS SAX, Electrical Engineer and Electric Light CONTRACTOR, RIDGMOUNT STREET, STORE STREET, LONDON, W.C.
Established 1855.
Specialities—Electric Bells, Burglar Alarms, Fire Alarms, Watchmen's Clocks and Fire Indicators combined, Water Gauges, Billiard Markers, Electric Vanes, Lightning Conductors, Speaking Tubes, Gas Lighters, Electrical Testing and Telegraph Instruments, Electrical Torped Apparatus.
Automatic Call Bells for Fire Stations, &c., fixed at all Stations under the control of the Metropolitan Board of Works
Cell Calls for Police Stations, Prisons, &c., as devised for and adopted by H.M. Home Office. Contractor to H.M. Post Office and War Office.
Electric Lighting—Domestic and Public. Estimates Free on Application.
Eight Prize Medals awarded.
Telephone No. 3848. Telegraphic Address: "*Sax—London.*"

THE LONDON ELECTRIC WIRE COMPANY, Ltd., ANCHOR WORKS, PLAYHOUSE-YARD, GOLDEN-LANE, LONDON, E.C. (Late of Wenlock-buildings, Ironmonger-row, E.C.
Specialities—Covered Wires of all descriptions for Electrical Instruments, Dynamo Machines, Bell and House Work, &c. Fancy Paraffined Wires specially prepared for Telephone and other indoor connections.

ADDRESSES.

LAURENCE, SCOTT & CO., Ltd., Electrical Engineers, Manufacturers, and Contractors, Gothic Works, NORWICH. Telegrams: "GOTHIC, NORWICH." See Advt., page ii., in last & next issues.
Specialities: THE SCOTT-SISLING SYSTEM is the best for all installations using accumulators; Circular sent on application.
THE NORWICH DYNAMOS are amongst the very best, Electrically and Mechanically. Numerous repeat orders prove superiority.
THE NORWICH SHIPLIGHTERS never give trouble.
SCOTT'S PATENT METER is accurate through a wide range.
COMPLETE CENTRAL STATIONS for Light and Power.
SCOTT'S PATENT INSTANTANEOUS FUSES are the best.

PHILLIPS BROS., Electrical Wire Manufacturers, The Lea Telegraph Works, HACKNEY WICK, LONDON, E., late of Macintosh-lane, Homerton Established 1870. Telephone No. 5422.
Specialities—Gutta Percha, India Rubber, Compound, Cotton, Silk, Flexible Cords, Telephone Wire, &c., &c. Multiple and other Wires. Special Wires for Dynamo Machines. Electric Light Leads, &c. Patent Non-Inflammable Insulation for Incandescent and Arc Lighting and Dynamo Machines.

PATERSON and COOPER, Electric Light and Power and Telephone Engineers. EUROPEAN WORKS, POWNALL ROAD, DALSTON (Near Haggerston Station) Contractors to H.M. Government, Leeds Corporation, &c.
Specialities—Phœnix Dynamos, Pilsen, Phœnix, and Clark-Bowman and J. F. Arc Lamps, Cardew's Voltmeter, Paterson's Electromagnet Am- and Voltmeter, Ayrton-Perry Am- and Voltmeters, Wallace Diamond Carbons, Switches, Safety Junctions, and Fittings for Arc and Incandescent Lighting. (Removed from 76, Little Britain, since Nov. 16, 1885.

largely depend on a process of selective acceleration of the meter.

On a future occasion, if you will allow me, I hope to add my suggestions for a method of charging.—Yours, &c.,

FRANK BAILEY.

17, South-street, Manchester-square, W.

ELECTRIC TRACTION AND LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is indeed a pleasure to congratulate English engineers who "do not need the assistance of Americans to show them how traction work should be done" (*The Electrician*, Vol. XXX., No. 757, p. 68). Although the novelty of Mr. Dickinson's trolley-rig might be questioned by those familiar with the Old Daft Road (P. Knoxville and St. Clair) at Pittsburgh in the early days of electric traction in this country, let us *hope* that the side trolley will prove a success, but let us await the verdict of a year hence.

As to the art of electric lighting (see your p. 107), why would it not have been a wise, if not an *ordinary English*, precaution to have used a *double pole switch* in the store?

Is it possible that you could have been misinformed as to stoppage of electric cars during thunderstorms, as per your leader on page 127, which reads:—"It is a *common custom* in the Western States to *stop all* the electric cars as soon as a thunderstorm begins," &c.? This will certainly be news to American engineers, for there are at least three lightning arresters on the market which can be relied on to protect the car motors perfectly, while this number could be increased were instruments admitted which, while offering protection to the motor, are themselves destroyed in giving it. Two of the protectors referred to have been procurable for at least three years past.—Yours, &c., J. STANFORD BROWN.

Camden, N.J., January 5, 1893.

["In many of our cities and towns, particularly in the "Western sections of the country, it has been common practice "during thunderstorms to shut down the plant, pull down the "trolleys, and wait till the storm shall have spent itself."—"Alexander Jay Wurts, *Electrical Engineer*, New York, November 16, 1892, p. 480.—ED. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is now in the press, and will shortly be ready. Firms and others who have not returned the slips asking for information are requested to do so *immediately*. The price of the Directory and Handbook will be as before: *Subscription*, 5s.; after publication, 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

TENDERS INVITED.—The Corporation of the Borough of Kingston-upon-Thames invite tenders for the construction, supply and laying down of the necessary plant and mains for the supply of electricity in the borough in accordance with the specification. Plans and form of tender to be obtained from Mr. Harold A. Winser, Town Clerk, after Tuesday next. Further particulars are given in our advertisement columns. Tenders must be in not later than February 11th next.

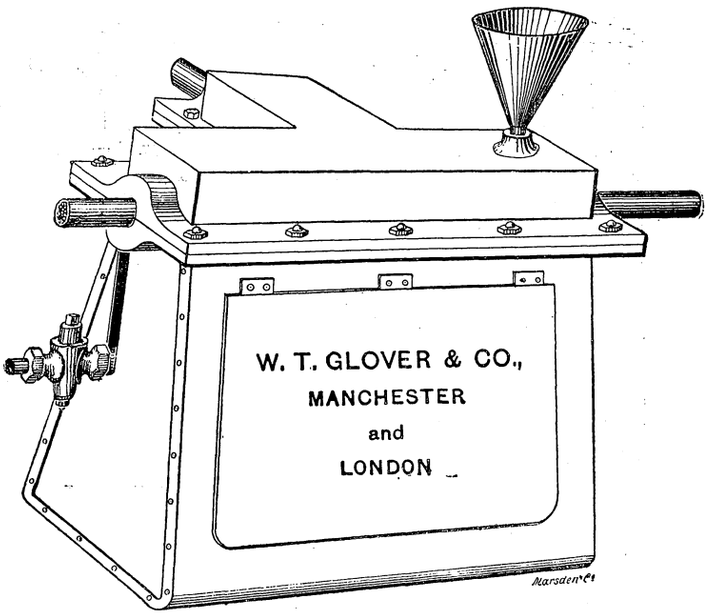
SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty announce in our advertisement columns that they have received instructions from the liquidator to sell by auction, in detail, on February 1 and 2, at the Globe Works, Whitley-street, Rochdale-road, Manchester, the whole of the plant of Messrs. Thomas Barraclough and Co. (Limited), in liquidation. Catalogues may be obtained, gratis, from the liquidator, Mr. Alfred Tongue, of 44, Brown-street, Manchester, or from Wheatley Kirk, Price and Goulty, Albert-chambers, Albert-square, Manchester, and 49, Queen Victoria-street, London, E.C.

SALE OF ELECTRIC TRAMCARS, DYNAMOS, &C.—A notice appears in our advertisement columns that Mr. John Jameson Truran, of 184, Gresham House, Old Broad-street, London, E.C., will receive offers for the sale by private contract, subject to the approval of the Court, of the electric tramcars, dynamos, working plant, tools, and sundry stores, used by the Electric Tramcar Syndicate (Limited), in connection therewith, and for the English and other letters patent connected with the undertaking. Tenders to be in by the 28th inst.

APPOINTMENT VACANT.—The Heckmondwike Local Board of Health require an engineer in connection with their electric lighting scheme. Particulars appear in our advertisement columns.

EDISON AND SWAN COMPANY.—It is gratifying to learn that pressure of business has necessitated the re-opening of the South Benwell Works, Newcastle-upon-Tyne, which have been closed for a considerable period.

GLOVER'S OPEN-AIR JOINTING APPARATUS.—We give below an illustration of an apparatus for making vulcanised joints, for which Messrs. Walter T. Glover and Co., of Salford, claim that ordinary or T joints can be vulcanised without bending or in any way altering their form. The apparatus has been in use for some time, and has, we understand, worked successfully. Full printed instructions for using the apparatus are issued by Messrs. Glover and Co., and can be obtained on application.



CATALOGUES.—Messrs. Ernest Scott and Mountain send us a catalogue of electric mining machinery, dynamos, motors, &c., which may be said to take its place amongst the numerous excellently printed calagogues which are now being prepared. The list includes complete instructions for fixing and working, approximate estimates and other useful information. Several examples of pumps and other appliances for mining machinery are illustrated and described.

——— Messrs. Cuttriss, Wallis and Co. (Limited) have just issued a new catalogue of their manufactures, which gives prices and particulars of the "Student's" dynamo, of the "Eclipse" and "Elmwood" dynamos and motors, and of the "Elmwood" gas-engine, which the Company claim is admirably adapted, combined with a special dynamo manufactured by the firm, for charging accumulators. Illustrations are given of the patent "dental" motor, and testimonials from users accompany the list.

——— Messrs. Mackey, Mackey and Co. forward us their illustrated catalogue of electro-medical and electro-surgical appliances, containing a very large number of illustrations of instruments, the majority of which seem to be adapted for electro-surgical use. As every surgeon seems inclined to invent his own instrument, there is an admirable choice of appliances for those who are liberal-minded enough to take advantage of the recent developments which have been made in this direction. Messrs. Mackey, Mackey and Co. are European agents for Messrs. Waite and Bartlett, of New York.

MESSRS. PYKE, HARRIS, AND CO. (LIMITED).—This firm have in hand the wiring and fittings for the electric light installation at the New Zealand Government Offices, Victoria-street, S.W.

Hosted by Google

FAILURE.—The following list of creditors is issued in the failure of James K. D. Mackenzie, electrical engineer, of Broadway-chambers, Westminster :—

Brougham, Hon. R., London	£600	0	0
Johnstone, J. B., London	54	0	0
Hayes-Eadler, Mrs., London	45	0	0
Kayler, Thomas, London	624	0	0
Mackenzie, Lady, London	100	0	0
Matheson, Sir Kenneth, London	250	0	0
Milne, T., London	55	0	0
Neate, Charles, London	750	0	0
Pam, Frederick, London	100	0	0
Rawson, F. L., London	125	0	0
Bankers' claim	60	0	0

And creditors of £30 and under.

DISCLAIMER.—In reference to the formation of the firm of Roger Dawson (Limited), we have received the following from Mr. Rashleigh Phipps :—"I notice in the electrical and building papers a statement that the Company styled 'Roger Dawson (Limited)' has been formed to acquire the business of Rashleigh Phipps and Dawson. As this is calculated to be detrimental to my interests, I beg to inform you that, although, under the terms of the dissolution between myself and Mr. Dawson, the property and assets of the late firm of Rashleigh Phipps and Dawson are assigned to him, the deed provides that neither partner shall use the name of the other in any shape or form whatever. I am now carrying on business at No. 102, Oxford-street, under the style of Rashleigh Phipps and Co., electrical engineers, and my business will be in no way affected by the Company which has been formed."

TESTING FACILITIES FOR GLASGOW AND DISTRICT.—The necessity for the periodical testing and overhauling of chains, slings, and other lifting and hauling gear, is now very generally admitted, and many users of such appliances make it a rule to have them officially tested and examined, and, if necessary, repaired at regular intervals. The Glasgow Anchor and Chain Cable Testing Company point out that the advantage of this is evident, as by it no doubt accidents are prevented, and when such do occur, the possession of certificates showing that the gear has been properly tested, and at suitable intervals, is generally a sufficient defence to employers against charges of neglect. They notify that new testing machinery, appliances, &c., at Lloyds' Proving House, are complete for efficiently carrying out the above work. They have now added to the above establishment a new Wicksteed's machine, which has all the improvements up to date.

ELECTRIC LAUNCHES.—The Thames Electric and Steam Launch Company, of which Mr. W. S. Sergeant is general manager, report that business is satisfactory. A large steam launch, of 73ft. beam, which the Company have on the stocks, is to be fitted throughout with the electric light, and is of special design, suitable for navigating the Thames, and canals in France, Belgium and Holland. This launch has been designed and moulded throughout by Mr. Sergeant. In addition, the Company are preparing a number of launches for the next season on the Thames, including two gigs for sailing, rowing, or electric propulsion. The Company's buildings and improved slipway at Twickenham are now completed.

AWARDS.—Messrs. Johnson and Phillips have been awarded a gold medal for dynamos at the recent Kimberley Exhibition. The machines were exhibited by Messrs. Edlin and Stevenson, who are Messrs. Johnson and Phillips' general agents in South Africa. ——Messrs. Ernest Scott and Mountain (Limited) have been awarded gold medals for the electric lighting of the Sheffield Trades Exhibition and of the Lincoln Trades Exhibition.

ELECTRIC HEATING AND COOKING.—Messrs. Crompton and Co. are issuing illustrated circulars giving particulars of their apparatus for heating, cooking, and other domestic purposes. Trade applications for these circulars should be addressed to 148, Brompton-road, S.W.

ELECTRIC NOVELTIES.—Messrs. Squire and Co., of South Molton-street, send us a sample of their night lamp, for which a charge of 2s. 6d. is made. The little lamp is of 1 c.p., and to prevent fusing a piece of fine wire is supplied. Care is necessary in using the lamp, and printed particulars are supplied.

CALENDARS FOR 1893.—The Commercial Cable Company issue a useful hanging pad calendar, showing their cable routes, and giving a considerable amount of information regarding cable rates, &c.

ELECTRO-HARMONIC SOCIETY.—A smoking concert will be given at the St. James's Hall Restaurant, Regent-street, W., on Friday next, the 27th inst, at eight o'clock.

ABERDEEN.—Mr. M'Whirter, of Glasgow, who has in hand an installation of the electric light at the Palace Hotel, Aberdeen, recently made an experiment with the electric light in the Denburn Valley, which has given such satisfaction to the railway company in the district that the whole of the main platform at the north end of the Denburn Valley station is, we understand, to be supplied with the electric light.

BELFAST.—Messrs. Siemens Bros. and Co. (Limited) have received a contract from the Harbour Commissioners to supply the necessary plant and apparatus required for the electric lighting of the quays on the County Down side of the harbour, including the Hamilton Graving Dock.

BIRMINGHAM.—A dinner was given last week by passengers using the electrical section of the Bristol-road tramway route to the drivers, conductors, and depot *employés*, the chair being taken by Mr. T. B. Goodyear, assistant traffic manager.

BLACKPOOL.—At the last meeting of the Town Council various recommendations by the Electric Lighting Committee came up for discussion, more particularly a contract recently given to Mr. E. Taylor for laying down iron street pipes for an electrical installation, and replacing and relaying the footway. It was urged by several members of the Council that, as Mr. Taylor's tender was not the lowest, it should not be accepted. After some considerable discussion the recommendations of the Committee, under which the Corporation themselves will do the work, were adopted.

BOMBAY.—In reference to the paragraph which appeared in our issue of the 13th inst., p. 311, it should have been stated that all the electrical power transmission plant for the Mannockjee Mills was both designed and supplied by Messrs. Charlesworth, Hall, and Co., whose Indian agents are Messrs. Wadia and Sons.

CHURCH LIGHTING.—S. Peter's, Hatton-garden, one of the most artistically decorated Roman Catholic churches in London, is to be lighted electrically.

CRYSTAL PALACE.—The National Cycle Show opens to-day, and a vast collection of cycles of all kinds will be on view.

DERRY.—We understand that the plans for lighting the City of Derry, which have been prepared by Mr. Blake, have received the approval of Dr. John Hopkinson, the expert called in by the Corporation.

DEWSBURY.—At the last meeting of the Town Council the minutes of the Lighting Committee were adopted. These included the report and specification of Mr. W. H. Preece, in which he recommends the establishment of the central station at the old gas works in Bradford-road, Dewsbury, and that provision should be made for the supply of current to 10,000 lamps, and also that the plant should be so arranged as to admit of easy extension at a future time. The Town Clerk was instructed to advertise for tenders for the work required to be done on the basis of Mr. Preece's specification.

ELECTRICAL TRADES UNION.—Mr. A. J. Walker, general secretary, informs us that this Union has now twenty-nine branches spread over the country.

HAMMERSMITH.—At the last meeting of the Vestry, it was decided to make experiments with the view, if possible, to use the refuse of the parish in generating electricity.

HECKMONDWYKE.—At the last Local Board meeting the Chairman of the Electric Lighting Committee moved that Mr. Hutchinson, C.E., should be appointed to prepare plans, specifications, &c., in connection with the Board's scheme for lighting the town with electricity. This resolution was, however, negatived, and it was decided to advertise for an engineer to prepare the necessary documents. (*See* advertisement columns.)

ILFORD.—The Brush Company are reporting to the Local Board on the question of lighting the district by electricity.

ISLEWORTH.—At the last meeting of the Heston and Isleworth Local Board it was agreed to appoint a committee of the whole Board to consider the defective supply of gas and its continued high price, and also to consider the desirability of obtaining electric or other light for the district. Should the electric light be selected, water-power will probably be utilised.

KIRKCALDY.—The Brush Electrical Engineering Company (Limited) are asking the Police Commissioners to sanction their application for a Provisional Order for the electric lighting of this town. After discussion it was agreed to remit the matter to the Roads, Streets and Bridges Committee to consider and report. The local Gas Company has, we understand, power under its articles to supply the electric light to the district.

LONDON INSTITUTION.—Prof. Silvanus Thompson delivered an interesting lecture to the members of this Institution on Thursday last week, this being the first of a series of lectures on Electric Lighting.

NANTWICH.—At the last meeting of the Local Board, meetings of the Lighting Committee and the special Sub-committee on electric light were fixed. These Committees have not previously met.

Hosted by Google

NEWCASTLE-UPON-TYNE.—At their last meeting the City Council agreed to the application of the Newcastle-upon-Tyne Electric Supply Company (Limited) for permission to apply to the Board of Trade for a Provisional Order, authorising the Company to supply electricity for all public and private purposes within the area of the City and County of Newcastle-upon-Tyne.

NEW ROMNEY.—A discussion arose at the last meeting of the Town Council as to the advisability of introducing the electric light. The price of gas in this district is 5s. 10d. for public lighting, and in excess of that amount for private consumers; and Mr. Hick, a member of the Council, strongly supported the introduction of the electric light in opposition to the Gas Company. It was resolved to form a committee for considering the expediency of lighting the town by electricity. The Gas Company have addressed a letter to the Council giving notice of termination of their contract for lighting the town by gas, which expires in May next.

REDDITCH.—The Local Board have under consideration the question of introducing the electric light. It has been complained that the reduction in the price of gas promised by the Gas Company has not been made. The proposal regarding the electric light was carried.

SOUTHAMPTON.—It has been decided to instal the electric light in the new buildings of the Free Library. The report of the Subcommitte appointed to consider the matter states that experience proves that whereas, when gas is used in such buildings, it is necessary to repaint and redecorate every three years, when the electric light is substituted, this period is extended to ten years. The damage to books is estimated in the report to be 40 per cent. of the total wear. The proposal to adopt the electric light was carried.

THE ROYAL ACADEMY.—The schools of the Academy in the basement of Burlington House are being provided with the electric light, and Messrs. B. Verity and Sons are proceeding with the work, the necessary alterations being under the supervision of Mr. P. H. Calderon, R.A.

SOUTHEND.—At the last meeting of the Town Council the recommendation of the Pier Committee that an additional engine, boiler, and dynamo be purchased, at a cost of about £780, in connection with the Pier Electrical Works, was approved. Mr. Alderman Hemmann took the opportunity of suggesting that the time had arrived when a considerable extension of the electric light could be made in the town and district. The discussion of this matter was, however, deferred, and a proposal to purchase a new set of tramcars for the pier was defeated.

SWANSEA.—Messrs. Wm. Foster and Co. (owners of the Morfa Copper Works, and who have recently taken over Pascoe and Grenfell's great works at Upper and Middle Bank, Swansea), in order to provide communication between the manager and heads of departments in the works, which are situate on either side of the River Taw, have taken out the old telephone wires which were stretched across the stream, and instructed Mr. John Legg, electrician, of Swansea, to put down a telegraph cable in the bed of the river, which has recently been successfully accomplished. The Silvertown Company have supplied the cable, and the work has been carried out to Messrs. Foster and Co.'s entire satisfaction. Gower-Bell telephones of the Government pattern have also been installed in the various departments.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The following is the report and accounts of the Directors of this Company for the half-year ended September 30, 1892, to be presented to the forty-first half-yearly ordinary general meeting of the shareholders, to be held at Winchester House, E.C., on Thursday next, the 26th inst., at one o'clock :

The revenue for the period amounted to £352,891. 0s. 7d., from which are deducted £98,797. 11s. 3d. for the ordinary expenses and £37,636 9s. 7d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £4,927. 7s. 7d. for income-tax, there remains a balance of £211,029. 12s. 2d., to which is added £661. 7s. 7d., brought from the preceding half-year, making a total available balance of £211,690. 19s. 9d. From this balance there have been paid :—

Interest on Debenture and Debenture Stock.....	£28,274	13	3
Dividend on Preference Shares	20,474	2	2
Two interim dividends of 2s. 6d. per share each on Ordinary Shares.....	100,000	0	0
	£148,748	15	5

Leaving a balance of £62,942. 4s. 4d., which is carried forward to the next account.

The revenue includes £33,431. 1s. 5d. dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish and the African Direct Telegraph Companies.

Since the last general meeting the Government of New Zealand has agreed that this Colony shall be included in the arrangement for reduced through rates to and from certain of the Australiasian Colonies and has joined with those Colonies in the guarantee. The guaranteeing Governments found that the reduced tariff during the first year resulted in greater loss than they anticipated, and to meet their wishes the Associated Telegraph Companies agreed to an increase of 9d. per word in the rates for ordinary telegrams. The new tariffs came into operation on the 1st inst.

In December last the Directors offered to the holders of the Company's Five per Cent. Debentures, redeemable at par in 1899, the option of exchanging their security for the Four per Cent. Mortgage Debenture Stock of the Company. The holders of the debentures have largely availed themselves of the opportunity thus given to them of acquiring this permanent security.

In accordance with the provisions of the Articles of Association, two of the Directors, George Garden Nicol, Esq., and John Denison Pender, Esq., retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The auditors, Mr. Henry Dever and Messrs. Welton, Jones and Co., retire, and offer themselves for re-election.

Direct United States Cable Company (Limited).

The following is a report of the Directors of the Company for the six months ended December 31, 1892, to be presented at the 31st ordinary general meeting to be held at Winchester House, E.C., on Friday next, at 12 o'clock noon :—

The half-year's revenue, after deducting out-payments, amounted to £43,629. 6s. 1d., as compared with £45,402. 0s. 8d. for the corresponding period of 1891, being a difference of £1,772. 14s. 7d. against the half-year under review.

The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £18,982. 3s. 7d., leaving a balance of £24,647. 2s. 6d. as the net profit, making, with £3,730. 8s. 1d. brought forward from the previous half-year, a total of £28,377. 10s. 7d. For the corresponding period of 1891 the working expenses and other payments amounted to £17,672. 16s. 5d.

Interim dividends of 3s. 6d. per share for the quarter ended September 30, 1892 (paid October 24, 1892), and of 3s. 6d. per share for the quarter ended December 31, 1892 (payable January 28, 1893), together amounting to £21,248. 10s., have been declared, and, after setting aside £4,000 to the reserve fund account, the balance of £3,129 0s. 7d. on the revenue account has been carried forward.

During the period under review, repairs have had to be made in both sections of the Company's cables at a cost of £6,301. 15s. 2d., which has been debited to the reserve fund account as heretofore, the balance of which, with the above addition, stands at £260,298. 6s. 1d.

A new station has been opened by this Company, in conjunction with the Western Union Telegraph Company, at 39, Mark-lane, London, E.C., where additional facilities are afforded both to the cabling public in that locality and to the Companies concerned.

The new permanent buildings at Ballinskelligs will shortly be completed

St. James' and Pall Mall Electric Light Company (Limited).

The following is the report of the Directors for the year ended December 31 last, to be submitted at the ordinary meeting to be held at the Company's central station, Carnaby-street, Golden-square, W., on Tuesday next, the 24th inst., at 3 p.m. :—

Owing to difficulties with regard to ancient lights and other matters, it was found impossible to complete the northern central station within the time contemplated. It is now, however, practically finished, and complete with sufficient machinery for the supply of 20,000 8-c.p. lamps, which, when necessary, can be augmented by further plant, raising the capacity of the station to 65,000 8-c.p. lamps. The two stations are already connected by the Great Trunk main, and within a very short time they will not only be able to run concurrently, but will be able to relieve each other should necessity arise.

The Directors are pleased to be able to report that the plant at the Southern Central Station is in perfect order, and fully maintains the efficiency and economy noted last year. It has, unaided, produced the income shown in the accounts. The Directors have devoted great attention to the curtailment of all unnecessary expenditure, in which they have been ably seconded by the officers and staff of the Company. Their policy has, however, been that of maintaining the buildings, plant, and mains of the Company in the highest state of efficiency. They are not only advised, but their experience has satisfied them, that to earn continuous dividends in a business of this character, liable as it is to many risks, and dependent on the correct handling of multitudinous details, it is essential that the whole of the Company's works and mains should be thoroughly maintained in every respect.

The whole of the compulsory mains are now laid, and this, together with the amounts required for the completion of the new station, has caused a large capital expenditure during the year, which has as yet produced no corresponding income. The Directors are happy to state that the works have been completed at a cost well within the estimates, and they do not anticipate that any further capital will be required unless a demand should arise for current in excess of the Company's present capacity.

The question of the "redemption fund," inaugurated last year, is one which has been prominently brought to the attention of the Directors by certain holders of founders' shares, who consider that the amount is improperly taken from "revenue account," and should be divisible as profit amongst the shareholders. This question was before the meeting of the members of the Company last year, when the creation of the fund was approved *nem. con.* The Directors, therefore, recommend that this policy be maintained, believing that it is one which will meet with the continued approval of the shareholders. In their judgment, the establishment of this fund is prudent, and they are advised that it is in strict accordance with law.

The Directors regret to announce that the action brought against the Company by Dr. John Hopkinson for the alleged infringement of his three-wire patent has been decided against the Company. Pending the consideration of whether the Company should appeal, they are glad to be able to state that they have completed arrangements whereby they will be in a position to continue the supply of current without interruption, and without further use of the patentee's system. The Company will not have to bear the whole of the costs of the action.

The net earnings of the Company during the past year have amounted to £14,598. 19s. Of this sum, £5,997. 10s. was distributed in July last in payment of an interim dividend at the rate of 5 per cent. per annum for the half-year ending June 30, 1892, on the Ordinary shares, and at the rate of 7 per cent. per annum on the Preference shares. The balance £8,601. 9s., together with the undivided profits of £22. 12s. 2d. from last year's account, leaves £8,624. 1s. 2d. now to be dealt with. The Directors propose to divide this amount as follows :—

(*a*) By payment of a dividend at the rate of 7 per cent. per annum on the Preference shares for the second half of the year	£3,500	0	0
(*b*) By payment of a dividend at the rate of 9½ per cent. per annum for the second half-year on the Ordinary shares, making, with the interim dividend paid in July last, a total distribution of 7¼ per cent. for the year	4,745	5	0
(*c*) By paying a dividend of £3. 3s. per share on the Founders' shares.....	315	0	0
(*d*) Amount to be carried forward to Ordinary shareholders' undivided profit account	59	7	0
(*e*) Amount to be carried forward to Founders' undivided profit account	4	9	2
	£8,624	1	2

Hosted by Google

The Directors have carried £1,000 to increase the Redemption Fund, which, with the addition of interest received during 1892, now stands at £2,029. 6s. 4d., and which is accumulating by annual additions towards representing loss of capital at the expiration of the term covered by the Provisional Order. The Directors are advised that the amounts provided in the accounts for depreciation are sufficient and ample for all purposes.

The Directors regret that Mr. Charles Showell, one of their number, found it necessary to resign his seat on the Board owing to his numerous engagements. They elected Mr. Gerald W. Balfour, M.P., brother of the Chairman, to fill the vacancy thus created, being of opinion that his services would be of great value to the Company. Sir John H. Morris, K.C.S.I., and Mr. Gerald W. Balfour, M.P., retire under Clause 79 of the Articles of Association, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and, being eligible, offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

HERCULITE AND ELECTRICAL MANUFACTURING COMPANY (LTD.).—This Company was registered on January 11th, with a capital of £12,000, divided into 4,000 £10 per cent. Cumulative Preference and 8,000 Ordinary Shares of £1 each. The objects are to adopt and carry into effect an agreement between James Lang, the Herculite Manufacturing Company (Limited), and Ernest J. Lunnon (the liquidator thereof), and this Company, for the purchase of the assets of the Herculite Manufacturing Company (Limited); to carry on the business of manufacturers of, and dealers in, the moulded article for the compound of which Mr. James Lang has taken out a provisional specification, Patent No. 3,240 (1892), and to carry on the business of electricians, engineers, ironfounders, blacksmiths, glass-blowers, and manufacturers.

PRINTING TELEGRAPH AND CONSTRUCTION COMPANY, OF THE AGENCE HAVAS (LIMITED).—This Company was registered on January 12th, with a capital of £130,000, in £5 shares. The objects are to acquire by purchase, or on royalty or otherwise, the exclusive or non-exclusive or limited right to use or vend within the Republic of France, and to grant licences for the using and vending of all or any of the inventions relating to printing telegraphs, whether covered by patent provisional specification or not; to enter into and carry into effect (1) an agreement already prepared and expressed to be made between Robert D. Radcliffe and Laur von Viben-Smith and the Company, and (2) an agreement between the Agence Havas, Robert D. Radcliffe, and Laur von Viben-Smith and the Company, with or without modification, but so that so long as such agreement shall be in force the sum of £20,000, part of the Company's capital, shall be appropriated and applied only in the manner and for the purposes specified in such agreement, except with the consent in writing of the Agence Havas; and to carry on in France, in conjunction with the Agence Havas, the trade or business of transmitting the news of the day to subscribers, and to buy, sell, and deal in all things incidental to improvements in telegraphy in France.

PYKE, HARRIS AND COMPANY (LIMITED).—This Company was registered on January 10th with a capital of £30,000 divided, into 1,400 "A" shares of £5 each, and 4,600 "B" shares of £5 each. The objects are, to carry on the business of electrical engineers then carried on by Messrs. Pyke and Harris, and to acquire, work, use and deal with in the following patents relating to the United Kingdom, viz.:—Nos. 11,503 of (1868), 3,900 (1890), 4,004 (1890), 22,785 (1891), 21,541 (1891), 17,818 (1891), and Provisional Protection, 19,222 (1892), and to carry on the business of manufacturing, repairing, selling and dealing in electrical machinery. Edward Prentice and L. S. M. Pyke are Managing Directors of the Company for a period of five years. Remuneration, £350 each per annum, together with a bonus of 5 per cent. per annum each upon the net profits, after the payment of a 10 per cent. dividend.

MISCELLANEOUS.—HARVEY STEEL COMPANY OF GREAT BRITAIN (LIMITED), iron and brass founders, mechanical, electric, and general engineers, &c.; capital, £180,000, in £10 shares.——HIRST, BROOKE AND HIRST (LIMITED), dealers in electrical, chemical, and scientific apparatus; capital £40,000, in £5 shares.——WELDLESS CHAIN COMPANY (LIMITED), iron and brass founders, mechanical, hydraulic, and general engineers; capital, £100,000, in £10 shares.——WILLIAM ACKROYD AND BROTHERS (LIMITED), iron and steel manufacturers, engineers, builders of steam, electrical gas, and other engines, &c.; capital, £130,000, in £10 shares.

ART WORKSHOPS (LIMITED).—A petition has been presented for the winding up of this Company, and is down for hearing at the Royal Courts of Justice, Strand, to-morrow (Saturday).

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA (LIMITED).—The annual return of this Company made up to January 1st has been filed. The Company was registered on June 18, 1889, with a capital of £50,000, divided into 9,500 "A" and 500 "B" shares of £5 each. At the time of making up 3,115 "A" and 500 "B" shares were taken up, of which the "B" shares were issued as fully paid—to Viscount Torrington (150); George Harrison and Alfred H. Whiffen, of Sydney, N.S.W. (200); and John F. Albright (150). Upon the 3,115 "A" shares the full amounts have been called, resulting in the payment of £15,020, and leaving £555 in arrears.

CRYSTAL PALACE DISTRICT ELECTRIC SUPPLY COMPANY (LTD.).—The annual return of this Company, made up to January 4th, has been filed. The Company was registered on June 30, 1883, with a capital of £100,000, in £10 shares, as "The Electric Construction and Maintenance Company (Limited)." By special resolution passed November 18, 1889, and duly confirmed, the name of the Company was changed to "The Electric Installation and Maintenance Company (Limited)." By special resolution passed December 3, 1891, and duly confirmed, the name was changed to its present title, and each of the £10 shares was subdivided into ten £1 shares. At the time of making up 31,850 shares were taken up, of which 17,430 were issued as fully paid. Upon the remaining 14,420 shares the full amounts have been called, and all calls (£14,420) paid. The shareholders include the Electric Construction Corporation (9,270 shares), J. E. H. Gordon (2,889), J. E. H. Gordon and Co. (1,056), Fowler-Waring Cables Company (1,040), Richard Hornsby and Sons (1,500), and J. Spencer Balfour (383).

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED.).—The first annual return of this Company, made up to December 27th last, has been filed. Out of a capital of £15,000, divided into 14,950 ordinary and 50 founders' shares of £1 each, 3,836 ordinary and 50 founders' shares have been taken up. Of these, 851 ordinary shares have been issued as fully paid, although no agreement explaining such issue has as yet been filed. Upon the 50 founders' shares the full amount has been called, and upon the remaining 2,985 ordinary shares 16s. per share has been called, resulting in the payment of £2,350. 10s., and leaving £361. 5s. in arrears. This payment includes £262 paid in advance of calls, and also £11. 15s. forfeited on two founders' and 116 ordinary shares.

OXFORD ELECTRIC COMPANY (LIMITED).—The first annual return of this Company, made up to December 23rd last, has been filed. Out of a capital of £100,000, in £5 shares, 94 shares have been taken up, and the full amount called, resulting in the payment of £412. 10s., and leaving £57. 10s. in arrears. A note at the end of the return states that, "in addition to the above shares, 6,800 shares are appropriated for the payment, on completion of the works in progress, under contract of August 13, 1891, made between this Company and the Electric Construction Corporation (Limited), London, E.C."

UNIVERSAL ARC LAMP SYNDICATE (LIMITED).—The statutory return of this Company, made up to November 30, 1892, has been filed. Out of a nominal capital of £3,000, in £1 shares, 2,865 shares have been taken up. Upon these shares a call of 1s. 6d. per share has been made, resulting in the payment of £228. 15s., which, however, includes the sum resulting from the payment of the £1 per share on 15 shares.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—The annual return of this Company, made up to December 15, 1892, has been filed. The Company was registered on April 22, 1890, with a capital of £70,000, in £1 shares. At the time of making up, all the shares were taken up, of which 56,756 have been issued as fully paid. Upon the remaining 13,244 shares the full amounts have been called, and all calls (£13,244) paid.

WILLIAMSON ELECTRICAL AND ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to December 22nd last, has been filed. The Company was registered on September 13, 1889, with a capital of £5,000, in £10 shares, to carry on the business of electricians, electrical and general engineers, and contractors, in New South Wales and elsewhere. By special resolution passed July 3, 1891, and confirmed July 21, 1891, the capital was raised to £25,000, in £10 shares, by the creation of 2,000 new shares. At the time of making up 500 shares were taken up, the full amount called, and all calls (£5,000) paid.

WOODFIELD SYNDICATE (LIMITED).—The annual return of this Company, made up to January 2, 1893, has been filed. The Company was registered on May 16, 1891, with a capital of £12,000, divided into 10,000 "A," 1,000 "B," and 1,000 "C" shares of £1 each. At the time of making up all the shares had been taken up, the full amount called, and all calls (£12,000) paid.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The following dividends will be recommended by the Directors of this Company at the meeting of the proprietors on the 27th inst.:—(1) A balance dividend of 17s. 6d. per cent. on the ordinary consolidated stock for the year ended December 31st; (2) a balance dividend of £1. 15s. per cent. on the preferred stock for the same period; both payable on the 28th inst., less income-tax. There will be a sum of about £737 carried forward. These dividends, with those already paid, will amount to £2. 15s. per cent. on the ordinary consolidated stock, and £5. 10s. per cent. on the preferred stock for the year 1892. The transfer books will be closed from the 13th to the 28th inst.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 15th were £1,007, as against £836 for the corresponding period of last year, being an increase of £171. The total receipts for half-year amount to £2,005, against £1,694 in the corresponding period of 1892, being an increase of £311.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company announce the payment of an interim dividend of 3s. 6d. per share, free of income-tax (being at the rate of 3½ per cent. per annum)

Hosted by Google

for the quarter ended December 31st last, the dividend to be payable on and after the 28th inst. £4,000 is placed to revenue, and £3,129 carried forward.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended January 13, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,664.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended January 15th were £2,522, as compared with £2,371 for the corresponding period of last year.

MORE THAN 1,000 PAGES OF RELIABLE MATTER. THE ONLY COMPLETE ELECTRICAL DIRECTORY.

"THE ELECTRICIAN"

Electrical Trades' Directory

AND

HANDBOOK FOR 1893.

SPECIAL NOTICE:—

RENEWED INSTRUCTIONS for 1893 from Advertisers in the 1892 Edition represent, up to January 25, no less than **96 per cent.**

NEW ADVERTISERS represent 30 per cent. over 1892.

SUBSCRIPTIONS to the 1893 Edition represent an increase of over 40 per cent., chiefly from Local Authorities and other large users of Electrical Machinery and Apparatus; and from the Colonies and India.

OLD FEATURES of the Book will be thoroughly revised and brought up to date.

NEW FEATURES of interest and value to the Electrical and Allied Trades will be added, and therefore New Advertisers and Subscribers for the 1893 Edition should send in their orders at once.

The Publisher especially requests the IMMEDIATE RETURN of the printed circulars asking for information from those who have not already sent them in.

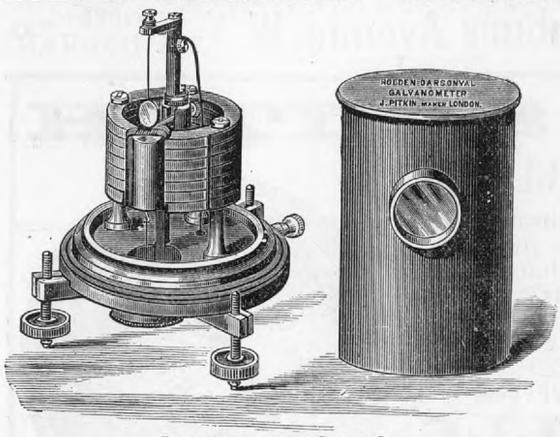
HOLDEN D'ARSONVAL UNIVERSAL DEAD BEAT REFLECTING GALVANOMETER.



INSTRUMENT WITH COVER OFF.

As supplied complete with Three Coils, Shunts, Resistances, and Self-locking Key, it is

The Best Galvanometer for Zero Testing.
The Best Galvanometer for Direct Measurements.
The Best Galvanometer for Measuring Large or Small Currents by the Shunt Method, from 1 to 1,000 Amperes.
The Best Galvanometer for Measuring E.M.F. from ·001 to 100 Volts.

Prof. W. AYRTON, Pres. I.E.E., speaking at the Institution on 26th Nov., 1891, said:—"*The deflection is larger than we have obtained with any other D'Arsonval of anything like the same size. . . . . Many times as sensitive as the Carpentier pattern for the same periodic time and resistance of coil. . . . . The method of construction has the great convenience that the coil, with its top and bottom supports, can be at once bodily withdrawn. . . . . .*"

As supplied to H.M. Govt.; The Central Institution; City Guilds; Electrical School, Chatham; R.A. College; Yorkshire College, &c.; and to Prof. Ayrton, F.R.S.; Prof. Fleming, F.R.S.; Sir T. Bazley, Mr. J. W. Swan, and many others.

By JOHN MUNRO, C.E., & Prof. A. JAMIESON, F.R.S.E., M.I.C.E., M.I.E.E.
NINTH EDITION, Pocket Size, Leather, 8s. 6d.

The NINTH EDITION has again been carefully revised and enriched with fresh matter, including several important communications by leading authorities on Electro-Technics.

LONDON: CHAS. GRIFFIN & Co., Limited., Exeter Street, Strand.

Just Published, Crown 8vo., 630 pages, with 350 Illustrations. 12/6 Cloth.

THE STANDARD
ELECTRICAL DICTIONARY

A Popular Dictionary of Words and Terms used in the Practice of Electrical Engineering.

Comprising upwards of 3,000 Definitions,

By T. O'CONOR SLOANE, Ph.D.
Author of "Arithmetic of Electricity," &c.

LONDON: CROSBY LOCKWOOD & SON, 7, Stationers' Hall Court, E.C.

CALVERT'S MECHANIC'S ALMANAC FOR 1893.

(Price 4d.) Contains, besides other valuable matter, "Patents: Some Popular Delusions," by W. LLOYD WISE, Esq., J.P., C.C., Fellow of the Chartered Institute of Patent Agents.

MANCHESTER: JOHN HEYWOOD, Deansgate; and JOHN CALVERT, 99, Great Jackson-street.
LONDON: JOHN HEYWOOD, 2, Amen-corner.

"THE PATENTEES' HANDBOOK,"

BY

J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,
CHARTERED PATENT AGENT,

Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.

(*Foreign Prices*).

—THE—

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS CO.,

LIMITED.

ELECTRICAL ENGINEERS,

AND

INDIA RUBBER AND GUTTA PERCHA MANUFACTURERS.

MANUFACTURERS OF

CABLES, WIRES, INSTRUMENTS, INSULATORS, DYNAMO MACHINES, MOTORS, ARC LAMPS & FITTINGS, BATTERIES, CARBONS, TORPEDO APPARATUS.

SPECIALITY.—Underground Electric Light System for High and Low Tension. The only System which has given complete satisfaction.

Contracts entered into for the Erection and Equipment of Central Lighting Stations, the Lighting of Ships, Factories, Houses, and the Supply of Complete Plant for Electrical Traction and Transmission of Power.

VULCANISED INDIA RUBBER.

HOSE, DRIVING BANDS, STEAM PACKING, WATERPROOF GARMENTS and FABRICS, SHOE SOLES, MATS, VALVES, BRAKE BLOCKS, WHEEL TYRES for CABS, CARRIAGES, BICYCLES, &c. SHEET, WASHERS, BUFFERS, SPRINGS, TUBING, SOLID CORD, FOOTBALL BLADDERS, LAWN TENNIS BALLS. MOULDED GOODS to any Pattern.

EBONITE.

Not affected by Vinegar or Hydrochloric or Acetic Acid.

SPECIALITIES IN EBONITE FOR CHEMICAL WORKS.

INSULATORS, BATTERY CELLS, SPEAKING TUBES, SHEET & ROD, SURGICAL APPLIANCES, PHOTOGRAPHIC ARTICLES, SCREW STOPPERS, PUMPS.

GUTTA PERCHA.

TUBING, BELTING, BUCKETS, BOSSES for FLAX SPINNING, GOLF BALLS, SHEET and TISSUE.

ESTIMATES & PRICE LISTS ON APPLICATION.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 767.—Vol. XXX. FRIDAY, JANUARY 27, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

After an interval of seven months, Prof. Dewar has again exhibited the wonders of liquefied oxygen and air at the Royal Institution, and has given an account of the further researches which have been made possible by the low temperature at his command. There is little news of electrical interest, beyond the fact that, while nitrogen is not magnetic, a magnet does not suck the oxygen out of liquid air. The condensation of the mercury vapour in a Torricellian vacuum lowers the tension at −80°C. to about 0·000,000,003 of an atmosphere. The resistance of metals and of alloys was, of course, discussed; and, in referring to the fall of resistance of carbon, and the fact, which we pointed out in October, 1892, that at a temperature of about 3,200°C. the resistance would vanish, Prof. Dewar was obliging enough to withdraw his old determination of 6,000°C. as the temperature of the arc, which, as we have already suggested, upset the coincidence. As radiant energy is now included in electrical science, we may note the ingenious method of keeping liquid oxygen when once it has been obtained. Prof. Dewar surrounds the vessel with a vacuum jacket. Still air is an excellent lagging; but it is essential that it be kept still. The smallest convection currents do mischief, as is well understood in refrigerated meat stores; if air cannot be kept still it had better be excluded. This is clear enough; but the leading daily journal, in an otherwise excellent "special article," deduces the conclusion and promulgates the announcement that no radiation can take place across a vacuum!

The meeting of the shareholders of the St. James and Pall Mall Electric Light Company was in many respects a remarkable one. As a rule, when a concern is paying an honestly earned dividend at the rate of 7¼ per cent. per annum, and is setting aside substantial sums for depreciation and something for redemption of capital, everything passes off with surprising smoothness. On this occasion, however, there was a determined attempt to force the Board into comparatively reckless financial courses, the amounts set aside for depreciation and the capital redemption fund being deemed detrimental to the immediate interests of the holders of founders' shares. It is a matter for satisfaction that it was finally decided to leave this subject to the discretion of the Board. In common with other electricity supply companies, the St. James is suffering from the increased wariness of its customers. During 1892 the lampage has grown by 24·4 per cent., but not so the gross revenue, that has exhibited the comparatively modest expansion of 10·4 per cent. The coal consumption has been diminished by ¼lb. per unit sold, while that of water has been reduced from 13·6 to 11·75lb. per lb. of coal. Although the consumption of energy has increased by some 10 per cent., the cost of fuel has remained stationary, and that of oil, waste, &c., has gone down. We trust the St. James Company will continue to run in this groove of prosperity and sound finance.

The financial result of the working of the City and South London Railway for the half-year ended December 31st last, shows an improvement upon that arrived at in the correspond- period of 1891. During the last six months of 1892, the passenger receipts amounted in round figures to £22,000, as against £19,800 for the last six months of 1891. On the other hand, the corresponding total expenses were in round figures £15,390 and £15,516. The outcome being a dividend at the rate of ⅝ths per cent. per annum to the ordinary shareholders. Since the opening of the line some two years ago, more than 11½ million passengers have been carried; and the figure for the last half of 1892, exhibits a 17 per cent. increase upon that for the corresponding period, the increase in train mileage being nearly 14 per cent. The locomotive and generating expenses per train mile run are now down to 7·1d.

Many of the "notes" which we have extracted from the Paper read by Messrs. Brew and Ledger at the Old Students' Association refer rather to the management of isolated plant than to the practice of supply stations, and the interesting observations on the coupling of compound-wound dynamos do not apply to ordinary central stations. But with plain shunt-wound dynamos conditions may easily arise which will cause unstable equilibrium of load or hunting of the engines. This subject was fully discussed in a series of articles in *Industries* in 1890. Abstracts will be found in Vol. XXV. of *The Electrician* under the title of "Coupling and Control of Dynamos at Central Stations." Where batteries are used, the sole advantage of compound winding, namely, that it allows the machines to be over-compounded to suit the feeders, disappears. The control of the voltage of a station does not appear to present any serious difficulties in practice. But considering the low plant factor of some stations—that is to say, the ratio of the actual output to the full load output of the same number of dynamos for a given time—there is reason

Hosted by Google

to suppose that the whole load is not so evenly distributed among the dynamos as is generally imagined. Some rather interesting experience on this point is recorded in another column under the title of "Non-Polarised Ammeters."

THE contribution to the obscure question of "stand-by" losses in boilers in Messrs. BREW and LEDGER'S Paper must be considered in connection with the fact that the steam-pressure was not maintained throughout the day, ready for running at short notice. No doubt some information from central station practice will be forthcoming before long, but these losses have their importance in isolated plant. It is difficult to see why they should be so much greater per hour in boilers which stand fourteen hours or so, than in ordinary factory boilers. These latter stand all night without attention, and without losing more than a pound or two of pressure. It is claimed for water-tube boilers that there is in them so little water to cool, that little coal is needed to bring them up to work again; but it is doubtful whether any other kind suffers so much by radiation. Lancashire boilers, of course, take up more room than can generally be spared, but a marine boiler could be lagged and French-polished all over if required. We should like to see some comparative figures of the "stand-by" losses of different types of boilers.

AN interesting discussion on three Papers on "Electric Traction" took place at a recent meeting of the American Institute of Electrical Engineers. The difficulty of dividing the current equally between two motors in parallel was alluded to, the problem being not unlike that of generating with two dynamos in parallel. Cases were mentioned in which not only did one motor do no work, but acted as a generator giving out 10 or 11 amperes. Mr. SPRAGUE believed that all fancy systems of traction, such as the series or double wire, were "practically dead, and we have come, on the 500 railroads in operation in the United States and elsewhere, to one single method of operation, a multiple arc system of distribution with a single wire overhead—and that is where we will stand." We are sorry to learn this, for it will render American experience in these matters of less use to us than ever, and, as in electric lighting, we shall have to design our stations and underground conductors as best we can. The opinion of the Mayor of Coventry may be taken as an indication of public opinion about trolley wires, at least in our towns, when he moved the adoption of the report recommending the Corporation "not to consent to such a system in Coventry under any circumstances whatever."

Mr. LEONARD'S ingenious suggestion of the use of a dynamotor in conjunction with a driving motor, described in *The Electrician*, Vol. XXIX., p. 200, did not meet with much approval during the discussion; nor did the great importance of a variable gear appear to be recognised. Dr. CHAS. EMERY described the use of a pump of variable capacity working a hydraulic motor, but it was not clear whether the pump was capable of a change of stroke, or whether a mere bye-pass was employed. Dr. EMERY, in describing the experiment, said that the fluid rapidly heated, although it circulated in 4in. pipes under a pressure of about 300lb. A large number of inventors appear to be at work on the problem in the United States. The Wenstrom hydraulic gear was alluded to in a note on page 1 of *The Electrician*, Vol. XXVI. We did not reproduce the description and illustration which appeared in American journals, since, after spending much pains, we could not make out the action of the parts from the drawing; but the principle was clear enough. There was a rotary oil pump and a bye-pass, and the effect was exactly that of a friction clutch. The whole of the work lost must be spent in heat. We do not think much of the bye-pass or friction clutch idea, but should be interested to see a variable gear constructed on the lines which we suggested in November, 1890.

THE substitution of a supply by meter at 6d. per Board of Trade unit, for a supply by contract at the rate of six shillings per ten-candle lamp per annum, has given rise at Bath to as near an approach to a riot as the inhabitants of that staid spa can be expected to venture on. Meters came generally into vogue on September 29th last, and the receipt of the bills for the Christmas quarter is alleged to have caused "a feeling of intense dissatisfaction" among certain consumers, chiefly tradesmen, and numbering only 7 per cent. of the total, the Company asserts. Had the City of Bath Electric Lighting and Engineering Company possessed a trained diplomat on its staff the blunder of switching over from a contract to a meter supply just as the dark days were beginning would not have been committed. The change should have been made during the dog days, and the consumers should have been brought gradually up to the fence. Lawsuits, public meetings, and boycottings are under weigh.

ON looking to see what type of meter was the source of this disturbance we rubbed our editorial eyes, for it is said to be one made by the Westinghouse Company, and is, therefore, presumably, the Shallenberger, the only meter for which the Board of Trade will go bail. The violence of the agitation would seem to render desirable the placing of certain eminent Board of Trade Electrical Standardising Laboratory officials under police protection. Seriously speaking, however, the Bath Company will do well to season the justice of its meters with a little mercy, for it was something in the nature of a sudden jump from a £5 to a £14 quarterly bill that made JOHN HAMPDEN take the field.

THE dangers of joking on serious matters are never more apparent than when we endeavour to liven up the tedious narratives of patent litigation by a little mild banter. During the LANE-FOX case we parodied a definition of an ampere-hour, but failed to explain with sufficient clearness that it was not solid fact. The definition, in consequence, was quoted by an American journal with some solemn remarks about newspaper science, and suggesting that the paragraph would have been "better suited for a humorous column in an electrical journal"! After giving the definition in full, our contemporary recommended the learned experts, who were supposed to be responsible, to "begin again by studying some ele-

Hosted by Google

mentary work on electricity," and ended with the unkind suggestion — "Possibly these are the English 'electricians' to whom we Americans are indebted for the many unjust, undignified, and untrue remarks about progress in the electrical industry in this country." Nor was this all: the "ampere hour" *badinage* found its way into a French journal; not directly from our columns, it seems, but having twice crossed the Atlantic. Such poor humour as the parody possessed was not, we think, lost in the French translation; but it was followed by "*Oh ma pauvre tête, oh le pauvre tribunal!*"

In our leading article last week on the result of the Hopkinson three-wire case we ventured to quote from Goldsmith's "Elegy on the Death of a Mad Dog." It seemed to be rather more appropriate than Shakespeare's "engineer hoist with his own petard." But Mr. Andrews calls upon us to withdraw it, since he thinks that it may be interpreted to mean that *he* went into the witness-box "to gain *his* private ends." Mr. Andrews' attention was called to the words by a friend, who apparently did not recognise them as poetical, but seems to have thought they were an effusion of our own. This is very flattering, but we must confess that they were not meant to be taken in desperate realism, and we will do the thing handsomely while we are about it, and withdraw the whole quotation, including the obvious allegation that Mr. Andrews went mad and bit Dr. Hopkinson. We trust this incident may now be considered at an end.

The Belgian Telephone System.—The telephonic system of Belgium has been formally taken over by the Government.

The Crossley Telephone Transmitter Patent.—This patent, No. 412, of 1879, expires on Wednesday next, February 1st.

Experimental Researches on Alternate Current Transformers.—We hear that Dr. Fleming's reply will not merely be printed in the *Journal* as was announced at the close of the discussion on his Paper, but that Thursday evening, February 9th, will be allotted to him.

Cable Interruptions—

	Interrupted.
Cayenne-Vizeu	September 24, 1892.
Senegal-Pernambuco	December 26, 1892.
*Lourenco-Marques-Mozambique ..	January 25, 1893.

*Communication with South Africa is still maintained by the West Coast route

Bedford.—A special meeting of the Town Council was held on Thursday last week for the consideration of the electric lighting of the borough. The following motion by Captain Verey was carried:—"That the Urban Sanitary Authority do not themselves undertake the electric lighting of this borough, but at once take steps to make arrangements with a private company, under conditions to be hereafter arranged."

International Inter-Communication.—At a lecture on Tuesday to the Young Men's Association at Wanstead by Mr. W. P. Forbes, on "The Collection and Distribution of News," telegraphic instruments were shown in operation, and a wire having been connected to the Direct United States Cable Company's system, a congratulatory message was sent from the hall to Mr. Grover Cleveland in New Jersey, and in a few minutes an appreciative reply was received from the President-elect.

Croydon.—The limited area of Croydon which it was proposed to supply with the electric light is not to be so supplied, at the present moment at any rate. On Monday night last week, the Croydon County Council had before them the proposition of the General Purposes Committee to spend the sum of £22,500 in the supply of electricity to a central part of the borough. After a long discussion the proposal was negatived, although only by the casting vote of the Mayor.

British Museum Reading-Room.—More complaints are appearing in the daily papers about the unsteadiness and hissing of the arc lamps in the British Museum Reading-room. As the lamps take thirty amperes and are arranged two in series on 130 volts, the cause is not far to seek. The conditions are probably more difficult than any other arc lamps in London. Thirty ampere arcs are not easy to regulate, and running lamps two in series is about as trying an arrangement as any that could be suggested.

Telegraphic Communication with Egypt.—A fierce hurricane has been raging in Egypt during this week, and has broken the cables between Alexandria and Malta and Alexandria and Port Said. The wires between Alexandria and Cairo are nearly all destroyed, but one direct cable is still working with Malta.—The Eastern Telegraph Company, however, under date of 26th inst., notify that their lines in Egypt are completely restored, thus re-establishing telegraph communication with Egypt, India, and beyond.

Electric Meters.—In the Westminster County Court on Wednesday, the case of the Metropolitan Electric Light Company *v.* Nathan came before Judge Bayley. The plaintiffs claimed £3. 17s. 4d. for 128 units of electricity supplied. The defence was that the amount charged for was more than was consumed. The plaintiffs said that under their Act of Parliament the meter index was conclusive. Whatever the meter registered the consumer was liable for. Judgment was given for the plaintiffs for the amount claimed, with costs.

The Practical Measurement of Alternating Electric Currents.—On Monday evening next Dr. Fleming will commence a course of four Cantor lectures on this subject. The course will include graphic representations of periodic currents, their analysis and synthesis, alternate current measuring instruments, laws of current flow in inductive circuits, the construction of non-inductive resistances, capacity effects, the measurement of alternate current power, alternate current meters, methods of measuring total output of alternate current central stations.

Derry.—The Local Government Board have intimated that they are prepared to permit an electric lighting loan of £15,000 at 3½ per cent. interest, the principal to be repaid by equal instalments extending over a period of twenty-five years. The Lighting Committee have decided to further communicate with the Local Government Board with the view of having the repayment of the loan spread over an extended number of years, but in the event of the Board being unable to do this the loan will be taken out at twenty-five years and the work proceeded with.

The Chicago Exhibition.—Mr. H. D. Wilkinson, whose series of articles on "Submarine Cable Laying and Repairing" many of our readers have no doubt read with interest, has been appointed engineer to the British Section of the Chicago Exhibition, and will sail on or about the 20th prox. Mr. Wilkinson is "an old Exhibition hand." At the Paris Exhibition of 1889 he was in charge of Messrs. Davey Paxman's fine exhibit, in 1891 he was responsible for the electric lighting of the Naval Exhibition, and at the Crystal Palace Exhibition of last year Mr. Wilkinson also held an important post.

Coventry.—At the last meeting of the Town Council, the consideration of the General Works Committee's report on the question of electric traction for the Coventry and district tramways, which had been adjourned from the meeting a month ago, was resumed. The Mayor moved the adoption of the report, which recommended the Corporation "not to consent to such a system in Coventry under any circumstances whatever." This motion was not carried, and the matter was referred back to the committee. The method objected to by the Mayor is the Thomson-Houston overhead trolley, which has been proposed by Mr. W. S. Graff Baker.

The Pacific Cable.—It is understood that the Premier of Victoria, Mr. J. B. Patterson, will enunciate the policy of the new Government at the meeting of the Melbourne Chamber of Commerce on Tuesday next. Mr. Patterson is said to be strongly opposed to the French project for constructing a line of cable from Australia to New Caledonia, as the first section

Hosted by Google

of the Pacific scheme. He urges that the several Chambers of Commerce throughout Australia should rather seek to co-operate with the projectors of the route *via* Canada in bringing pressure to bear upon the Imperial Government to facilitate the adoption of that line for the duplicate cable which is regarded as desirable.

Obituary.—The death is announced, at Melbourne, on the 11th ult., of Captain F. C. Rowan. Captain Rowan, who was only 47 years of age, was born in England and educated in Canada, where his father, who was an engineer, built the first railway in that dependency. He was educated for the army, and went to Victoria about 20 years ago, where he entered into business. Having always a keen interest in scientific matters, he became connected with the electric lighting movement, and became manager of the Australasian Electric Light, Power, and Storage Company. About three years ago the Company was bought by the Brush Company, and Captain Rowan continued his management under the new proprietary.

Windsor.—In reference to our note on p. 320 of our last issue respecting the Windsor electric lighting difficulty, it is necessary to explain that it is not the Corporation, but the Windsor and Eton Electric Light Company who are seeking to introduce the new illuminant to the Royal borough; and also that since the recent police-court proceedings the Company have not attempted any further opening up of the streets without permission. On the contrary, being asked by a leading tradesman to connect his premises with their mains on the opposite side of the street, the Company applied to the Corporation for leave for this purpose, and it was over this application that the wrangle in the Town Council arose, to which we referred last week. The Corporation have not yet accorded the permission asked for

The City Lighting.—In the course of his address to the Commissioners of Sewers, reviewing the past year's work, Mr. Alderman Treloar referred in the following terms to the City lighting :—

> Great progress has been made with electric lighting, and, indeed, the street lighting in all the main thoroughfares is virtually completed ; the side streets it is proposed eventually to light by means of glow lamps. I am sorry to say that, as regards the private lighting, we are much behind, and every effort should be made to press this on. The City of London Electric Lighting Company, in laying their tubes, took the opportunity, in a very enterprising manner, of placing other tubes sides by side with them, not only sub-terra but sub-rosa, with the view of ultimately using them for telephonic purposes. They cannot, however, so use these extra tubes without the consent of the Commission. Negotiations are now in progress to obtain from the company some practical advantage for the ratepayers before we give our consent.

The City and South London Railway.—The following letter, signed T. W. Ockenden, appeared in the *City Press* of Wednesday last :—

> Sir : The utility of this railway would be further increased if the Directors would have the seats in the carriages taken away altogether. At present there is sitting accommodation for 16 in each compartment. By mutual squeezing 20 find sitting space somehow. On the journey to town from 13 to 20 more passengers are packed in by the Company's ever-loyal turnkeys. The new arrivals stand, some of them on one leg, and balance themselves by clinging to a rail courteously placed for the purpose in the low roof overhead. It is manifest that the seats are simply an obstruction, and if removed more heads of human cattle could be conveyed, to the obvious advantage of the Company's exchequer. Now and then the lights go out, and some day, when the train comes to a standstill, if a panic should happen amongst the people thus wedged together and locked in, with all chance of escape cut off, perhaps some lives will be sacrificed, and then probably the Company will treat their patrons with more consideration

Nottingham.—On Thursday, the 12th, the new technical schools were opened with considerable ceremony, speeches being made by Lord Belper, Prof. Stuart, M.P., and the Postmaster-General. Subsequently the buildings were thrown open to the public, who manifested the greatest interest in the exhibits of local industrial products, and machinery of various kinds in motions, which had been got together by Prof. William Robinson. Amongst the electrical exhibits were some by the Brush Company, Crompton and Co., Nalder Bros. and Co., Mr. R. W. Paul, J. H. Holmes and Co. (Newcastle). The dynamo room contains a 30 H.P. compound vertical high-speed steam-engine, coupled direct to a dynamo generating current for lighting the entire building. The electric lighting plant was supplied by the Brush Company at cost price. The wiring was carried out by the senior students of the College, and a foreman from the Brush Company. In the dynamo room there is also a petroleum oil engine, supplied to the Committee at half-price, by Messrs. Priestman Brothers, Hull. This engine drives the various dynamos for testing purposes.

The Decimal System.—On Wednesday a deputation, representing the New Decimal Association, the chambers of commerce, and trades unions, as well as various scientific and educational institutions, waited upon the Chancellor of the Exchequer, at the Treasury Offices, for the purpose of urging upon the Government the adoption of the decimal and metrical system of weights, measures, and coinage, or to appoint a committee of inquiry into the subject. Amongst those present were Lord Kelvin, Sir Henry Roscoe, Sir A. K. Rollitt, Dr Gladstone, Sir Philip Magnus, Mr. J. Emerson Dowson, Mr. A. E. Siemens, and Major-General Webber. The Chancellor of the Exchequer said it was quite unnecessary to convince him that the decimal system was good. The point to be considered, however, was the practicability of its adoption at the present moment. So far as he knew, no great change in the currency which governed the wants and the habits of the mass of the people had ever taken place except in coincidence with some great revolution. A decimal system was introduced into Europe by the great French Revolution. The change in Germany took place, not in quiet times, but as a result of a great war and a great change which constituted the unification of Germany. He belived even in the United States the change was made consequent upon the establishment of the Federal system. There was no doubt of the theoretical merits of the system. Mr. Gladstone established the florin for the purpose of breaking ground and opening the way for a decimal system. Unfortunately, the florin had become the most unpopular coin in the country, and they were at present issuing half-crowns because they were preferred to the florin. He wished the deputation every success in the work in which it was engaged, but in his opinion the time had not yet come in which the Government could with any advantage undertake to operate upon a subject for which the great mass of the public was not prepared.

Electric Meters at Bath.—Some of the customers of the City of Bath Electric Lighting and Engineering Company are complaining of the action of the Directors in having departed from the contract system, and substituted meters. The receipt of the bills for the Christmas quarter, says the *Bath Argus*, greatly surprised several of the customers by reason of the unlooked-for excess of the charge by meter as compared with the sum hitherto paid under the contract system. One tradesman had contracted for a supply for £22 a year, and last quarter's bill, when the charges were made according to meter, amounted to only about £3 less than the sum for which a year's supply was originally contracted for. In the corresponding quarter of 1891 another firm was charged £5, and for the three months ending December, 1892, they had to pay £14. Another paid nearly £8, as against £2. 10s. by the contract system. In the case of one Milsom-street establishment the Christmas quarter account comes to £15. 10s., whereas the contract price per quarter is only £11 ; and in another city business, where the contract is for 36s., the last demand amounted to considerably over £4 for the quarter. It is said that many will refuse to continue the light unless some reduction in the price takes place, although private consumers in Bath pay less per Board of Trade unit (6d.) than those in other towns. Some of the consumers say that they would never have entertained the idea of having the light laid on had the probability been held out of such a change taking place, it being represented at the time that the uniform charge of 6s. per annum for a ten-candle power lamp would be cheaper than the price of gas, and that the Company would be able to pay a substantial dividend at this charge for consumption. Some of those who entered into contracts with Mr. Massingham had a proviso added to the agreement to the effect that no increase should be made in the charge for the first seven years, and in these cases the consumers are exempt from the meter arrangement. A public meeting will probably be held.

ELECTROMAGNETIC THEORY.—XLIII.

BY OLIVER HEAVISIDE.

(*Continued from page 270.*)

§. 181. Still keeping to a simple dielectric, we may always, by consideration of the fact that the speed of propagation is v, find the form of the wave-front due to any collection of point-sources, and trace the changes of shape and position it undergoes as it progresses. For obviously, if a point P be at a distance vt from the nearest source, no disturbance can have reached P from it if it started into action *after* the moment $t=0$; and generally, the effect at P at a given moment arising from a particular source depends upon its state at the moment r/v earlier (if r be the distance from the source to P), and upon the previous state of the source, causing residual or cumulative action at P. We therefore know the limiting distance of action of the sources for every one of their momentary states. The wave-front belonging to a set of disconnected point-sources consists initially of disconnected spheres. But as they expand, they merge into one another to form a continuous extreme wave-front consisting of portions of spheres. When the point-sources are spread continuously over a surface to form a surface-source, we have a continuous wave-front from the first moment; or rather, two wave-fronts, one on each side of the surface. There is an exception, to be mentioned later, when the sources send waves one way only from the surface. This is not the already described case of the cancelling of two trains of waves at particular frequencies, but is a unilateral action obtained by a special arrangement of surface-sources. Passing over this, observe that when we have once got a wave-front we may ignore the sources which produced it, and make the wave-front itself tell us what its subsequent history will be. For, to trace the course of the wave-front from one moment to the next, we have merely to move any element of the surface in the direction of the normal to that element through a small distance a to obtain the new position at the moment a/v later. This being done for the whole surface, gives us the new position of the wave-front, and by continuing this process we may follow the wave-front in its progress as long as we please. Thus the wave-front coming from the surface of a sphere is a sphere; from a round cylinder, if infinitely long, also a round cylinder; but if of finite length, then a cylinder with rounded ends; from a cube, initially a cube with rounded corners, but becoming more and more spherical as it expands; and so on. It is easily seen that at a sufficiently great distance from a finite collection of sources of any kind, the wave-front tends to become spherical, or the complex source tends to become equivalent, at a great distance, to a point-source of some complex kind.

§ 182. Now consider the effect of an obstacle brought into our medium, say a non-conducting dielectric mass of different inductivity or permittivity. The manner of propagation in it is similar in kind to that in the external medium, but it varies in detail, and the speed will usually be different. Then, when we have a wave coming from (say) a point-source in the first medium, the presence of the obstacle at first makes no difference. It has no immediate action, and, until the wave reaches it, might as well not be there. But immediately the wave does reach it a change occurs. The interface of the two media becomes the seat of sources of fresh disturbances, or they may be considered fictitious sources, in contrast with the original, for they do not bring in any fresh energy. Thence arises a new effect, viz., reflection. Not the whole, but only a part of the wave disturbance enters the new medium. The rest is thrown back, and forms a reflected wave. In the same way as we may trace the course of primary waves from a source in a uniform medium may we trace the course of the secondary waves set up by the obstacle. The disturbance outside it is then due to the superposition of the primary and secondary waves, and, if there be just one obstacle, this state of things continues. Of course the secondary wave-front may itself be complex, because the disturbances going into the second medium and transmitted therein according to its nature, may reach the interface again at other parts, and there suffer reflection and transmission anew. This complication is done away with by making the obstacle infinitely big, with a plane boundary. Then we have just one wave in the obstacle and two in the medium containing the source, viz., the primary and the first (and only) reflected wave.

But if there be a second obstacle, not only will it, like the first, give rise to a secondary wave when the primary meets it, but each obstacle will act similarly towards the secondary wave from the other, whence arises a pair of tertiary waves, and so on. Thus, with only two obstacles, we shall have a succession of infinitely numerous waves crossing and recrossing one another, arising out of the action of a point-source, with great complications. But, however complex in detail, we have the important fact that the mere knowledge of the speed of propagation allows us to lay down the whole course of the waves generated, and the position of the wave-fronts belonging to a given epoch at the source. The mathematics of the full treatment may be altogether beyond human power in a reasonable time; nevertheless, we can always predict with confidence that the results must have such and such general properties relating to the course of the waves, besides the properties involved in the persistence of energy.

In the above we were concerned with discontinuous heterogeneity, or an abrupt change in the value of one or both of the constants c and μ at an interface. When the medium is continuously heterogeneous, or the "constants" change in value continuously from place to place, then the speed v is made a function of position. The process of partial reflection and partial transmission which occurred at the interface now takes place in general wherever the value of c or μ changes. These changes being continuous, so are the results, so that we do not have distinctly separable trains of waves, but rather a continuous distortion. We can, however, follow the course of a wave expanding from a point by communicating to the wave-front the speed proper to its position, such speed being, as above, definitively known. A spherical wave may remain spherical, only varying in its speed; or more likely, it may change its form as it expands. It may become ellipsoidal, for example, and of course must do so if the speed in different parts of the medium vary suitably.

It is possible for the inductivity and permittivity to change, either abruptly or continuously, without any reflection, or casting behind of the disturbance as a wave progresses, although its speed varies. In such a case it will be found that the ratio μ/c is constant. The change in μ, or the ratio of induction to magnetic force, then fully compensates the change in c, the ratio of displacement to electric force, either of which changes by itself would cause reflection.

In connection with a heterogeneous medium (including abrupt changes of nature), we may notice its behaviour as regards steady states, in contrast with that of a thoroughly homogeneous medium. In the latter case, as we have already described, the introduction of a steady point-source causes the steady state to begin immediately at and spread around it, after which no change occurs. That is, the medium being homogeneous, there is no reflex action. But when it is heterogeneous the case is quite different. The steady state of displacement due to impressed voltage depends upon the permittivity in all parts of the medium, and only comes about as the final result of the infinitely numerous reactions between different parts, due to the reflections that take place, which modify the final distribution of displacement as well as (usually) the total amount. There is a similar contrast in the mechanism of the mathematics involved in the calculation of the steady state. When the medium is homogeneous we may find it through the potential of fictitious matter at the source alone. When heterogeneous, we require to have fictitious matter all over the medium, or rather in all parts where it changes its nature, and, owing to the infinitely numerous reactions, we should, in a general or complete solution, require to perform not one space-integration, but an infinite series of successive space-integrations, before we could arrive at the true potential function, allowing for the variations of permittivity everywhere. Thus, by electromagnetic considerations we obtain some insight of the true nature of transcendental static problems, involving potential functions and assumed instantaneous action at a distance.

§ 183. When the medium is not isotropic as regards either the displacement or the induction, or as regards both, we have very remarkable effects, known in the science of optics as double-refraction. There can be two distinct wave-speeds for a given position of the wave-front, and these speeds change when the direction of the normal to the wave-front changes. Hence double refraction, or the separation of a wave entering an eolotropic medium into two waves travelling independently of one another at different speeds. If the medium is only electrically eolotropic, although the displacement and induction are still in a wave-front (of either wave), and are perpendicular to one another, the electric force is inclined to the wave-front, so that the ray, which indicates the direction of the flux of energy, is inclined to the normal to the wave-front. Similarly, with magnetic eolotropy alone, it is the magnetic force that is inclined to the wave-front. When the medium is both electrically and magnetically eolotropic, both the electric and the magnetic force are inclined to the wave-front, whilst the displacement and induction, though still in the wave-front, are no longer perpendicular to one another.

By imagining plane electromagnetic sheets to traverse the medium in all possible directions about a point, and comparing their positions with respect to the point at equal times after crossing it, we arrive at the conception of the wave-surface. This is obviously a sphere in an isotropic medium. But when it is eolotropic, the two speeds, and their variation according to the direction of motion of the waves, make the wave-surface become a very singular double surface. With electric eolotropy alone, which is the practical case, it is Fresnel's wave-surface. It is also another Fresnel surface with magnetic eolotropy alone. But when the medium is eolotropic as regards both the induction and the displacement, the wave-surface is of a more general and symmetrical character, including the former two as extreme examples. It is still a double surface, however, except in one case. We have already mentioned that in an isotropic medium there is a peculiar behaviour when the ratio μ/c is constant, although μ and c vary. We might anticipate some peculiarity in the wave-surface when μ/c is constant. This constancy now means that the directional properties of μ are exactly paralleled by those of c. That is, the principal axes of μ and those of c are coincident, whilst the value of the ratio of the permittivity to the inductivity is the same for the three axes. The result is to reduce the double wave-surface to a single surface, which is an ellipsoid.

Assuming light to consist of vibrations of an "elastic solid" medium, single or ordinary refraction is explained by an alteration in the density or the rigidity of the ether. Not only is the theory quite hypothetical in considering the kinetic energy to be the energy of vibrational motions of displacement, but the alteration of density or rigidity assumed is a further hypothesis on the top of the main one, for there is no evidence that there is such a change. Moreover, the explanation will not work properly. On the other hand, the electromagnetic theory says that light consists of electromagnetic vibrations in the ether. This, too, is a hypothesis. But the auxiliary part, that refraction is caused by change of permittivity from one medium to another, is not a hypothesis, but a fact. Moreover, the theory works.

Similarly, double refraction in elastic solid theories of light is explained by eolotropy as regards elasticity, or by something similar relating to the density. This is also hypothetical, and not without its troubles. But, on the other hand, Maxwell declared that double refraction occurs because the doubly refracting medium is electrically eolotropic. Now this is a fact too, and the theory is a clear one.

These remarks will serve to illustrate what I mean by the far greater intrinsic probability of the electromagnetic theory, apart from the experimental work of late years. It is much less hypothetical than elastic solid theories. We know nothing about the density or the rigidity of the ether, or how they vary in different bodies, or if they vary. But we do know a good deal about electric permittivity and magnetic inductivity. Instead of dealing with possibilities, we are dealing with actual facts.

The old objection that a mechanical theory of light was surely to be preferred to an abstract electromagnetic theory was very misleading. The electromagnetic theory is mechanical, without, however, a precise specification of the mechanism. An elastic solid theory is merely a special mechanical theory. It cannot satisfy the electromagnetic requirements, but this failure, though immensely important in itself, is not the point here. Even if it did satisfy them, it would probably be less true than the electromagnetic theory, which, being abstract, does not assert so much. There may be many "mechanical" solutions of an abstract theory. Elastic solid theories are a great deal too precise in saying what light consists of, and mechanical speculations in general should be received with much caution, and regarded rather as illustrations or analogies than expressions of fact. We do not know enough yet about the ether for dogmatising.

One can imagine that a clear-headed man might be able to work his way through all the theories of light yet propounded, assimilate what was useful and true, eliminate what was useless or false, and finally construct a purified theory, not professing to explain what light is, but still connecting together in a perfectly unobjectionable manner, free from hypotheses, all the principal facts, and of so compliant a nature as to readily adapt itself to future discoveries, and finally settle down to a special form expressing *the* theory of light. It is hardly likely that the clear-headed man will be found for the purpose, and perhaps his theory would not be very popular. It would be so very abstract. What is far more likely is that the electromagnetic theory (itself abstract and possessing many of the desired qualifications), which has already begun to find its way into optical treatises at the end, will gradually work its way right through them to the beginning, and in doing so, oust out the most of the old-fashioned hypotheses. The result will be to have optical theory expressed throughout in electromagnetic language. To do it properly, it is hardly necessary to say that the preposterous 4π, which the B.A. Committee seem to want to perpetuate, should be ignored from the beginning.

§ 184. So far, in varying the nature of the medium, we have not introduced any property causing its local waste, such as the existence of conductivity (finite) necessitates. In all the varied journeys of electromagnetic waves in a (theoretical) non-conducting dielectric with non-conducting obstacles there is no waste of energy, and the work done by impressed forces is entirely accounted for by the electric and magnetic energy. Assuming a certain amount of work done up to a certain moment, and none later, that amount expresses the energy of the electromagnetic field, and, however it may vary in distribution, the total remains the same, just as if it were a quantity of matter moving about, having continuity of existence in time and space. The useless complication introduced by the circuital indeterminateness of the energy flux may be ignored. The only way, then, to get rid of the energy is to absorb it at the sources by working against impressed forces. Putting that on one side, there is the waste of energy by dissipation in space, which cannot be stopped. The energy is still in existence, and is still in the electric and magnetic forms, and must always be at a finite distance from its source and an infinite distance from infinity; but since it gets out of practical reach, and is constantly going out further, it is virtually wasted. Thus, ultimately, the energy of all disturbances generated in a boundless non-conducting dielectric goes out of range and is wasted.

To prevent this, we may interpose a reflecting barrier. Imagine a screen to be introduced, at any finite distance, enveloping the sources, of such a nature as to be incapable of either transmitting or absorbing the energy of waves impinging upon it. Then clearly the dissipation of the energy is stopped, and it all keeps within the bounded region. The waves from the source will be reflected from the boundary, and their subsequent history will be an endless series of crossings and recrossings. The only way to destroy the induction and displacement is to employ artful demons (or impressed forces), so situated and so timing themselves as to absorb the energy of waves passing them, instead of generating more disturbances. In the absence of this demoniacal possession of the region, the energy will remain within it in the electromagnetic form and be in constant motion.

But any opening in the screen, establishing a connection through ether between the inner and outer regions, will at

Hosted by Google

once put a stop to this local persistence of energy. For energy will pass through the opening, and once through, cannot get back again (though a part may), but will escape to infinity. A mere pinhole will be sufficient, if time enough be given, to allow all the energy to pass through it into the external region, and there go out unimpeded to an infinite distance, in the absence of a fresh complete screen to keep it within bounds.

A screen to perform the above-described functions may be made of that very useful scientific substance, the perfect conductor, which is possibly existent in fact at the limiting zero of absolute temperature, the latest evidence being the recent experiments of Profs. Dewar and Fleming, measuring the resistances of metals at very low temperatures. If a perfect conductor, it is also a perfect obstructor, or is perfectly opaque to electromagnetic waves, without, however, absorbing their energy superficially.

(To be continued.)

THE LAUFFEN-HEILBRONN TRANSMISSION.

An interesting pamphlet has been forwarded to us containing a full description of the Lauffen-Heilbronn Transmission, the first, we believe, to utilise the three-phase system for the purpose.

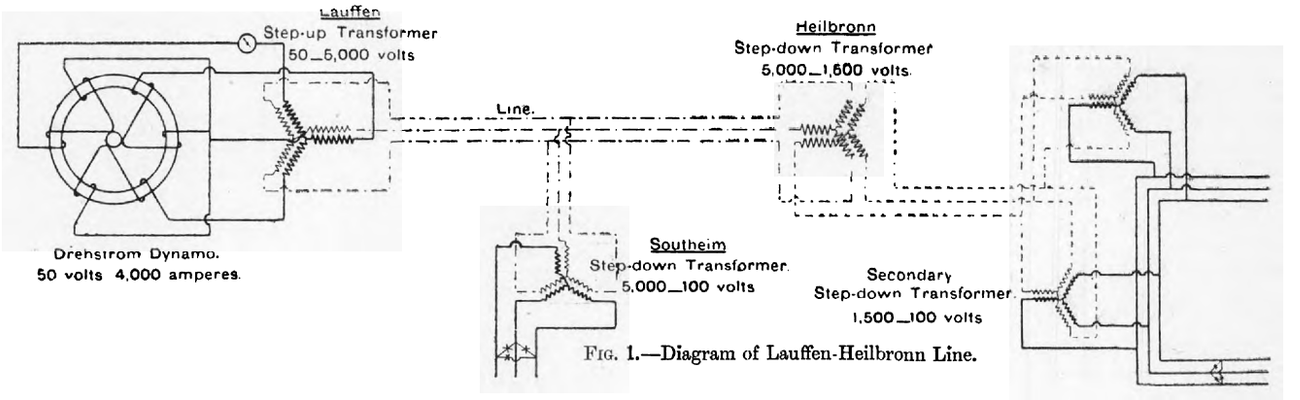

FIG. 1.—Diagram of Lauffen-Heilbronn Line.

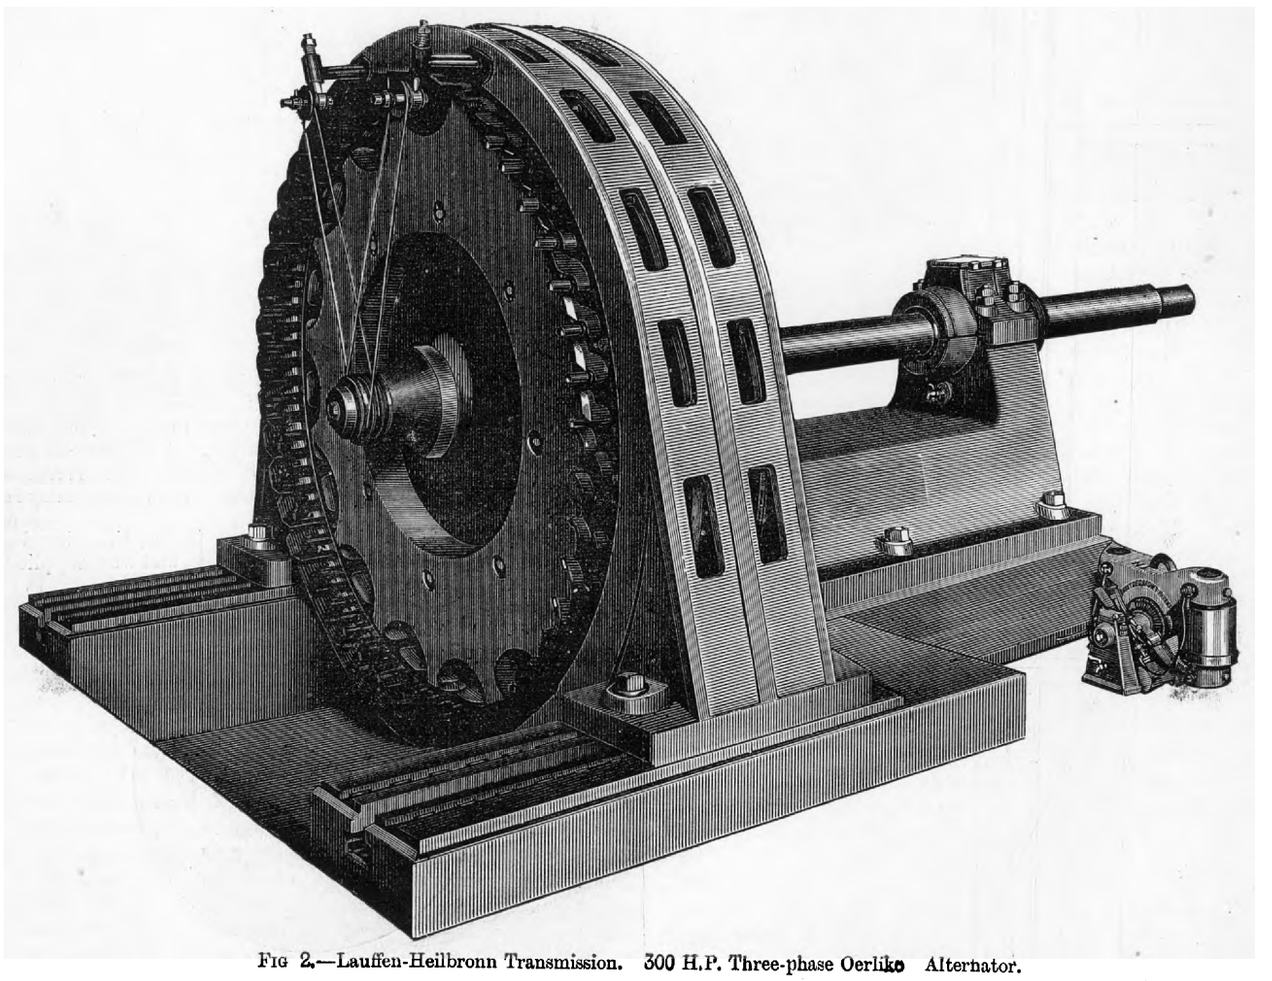

FIG 2.—Lauffen-Heilbronn Transmission. 300 H.P. Three-phase Oerlikon Alternator.

The Wurtemberg Portland Cement Works at Lauffen-on-the-Neckar determined towards the end of 1889 to utilise their superfluous water-power (about 900 H.P.) for lighting and supplying power to the town of Heilbronn, some six miles off, and selected the plans of Mr. Oskar von Miller, who proposed to use the three-phase system, which was then coming to the fore. The work was begun on September 15 1891, by the erection of the condu and laying of the cables, and on January 10, 1892, the current first sent out by the station. The power available is sufficient

bout 15 per cent., of which 10 per cent. is in the transmitting wires, and 5 per cent. in the distributing network.

sion to Heilbronn, and reduced at the latter place to 1,500 volts, and led into the high-pressure network. From this primary network the pressure is reduced to 100 volts in a secondary set of mains, which supply the house illumination. About half-way from Lauffen to Heilbronn is the village of Sontheim, which is also supplied with current. The pressure is there reduced directly from 5,000 to 100 volts.

The turbines—only one of which is now in use, the other being being kept in reserve—are of the vertical type, and were supplied by

the Maschinenfabrik Geislingen. As tested at the time of the Frankfort transmission, these turbines give 330 H.P., with 12ft. 6in.

Hosted by Google

head. The speed is kept constant, by hand regulation, at 35 revolutions a minute. The dynamo is a three-phase machine by the Oerlikon Works, and is geared to the turbine by bevel gearing. This is the machine that was used for the Lauffen-Frankfort transmission, and was fully described in *The Electrician*, Vol. XXVII., p. 381, from which we reproduce Fig. 2. At the time of light load the superfluous energy is utilised for drying the clay used in the Portland Cement Works. It has been found cheaper to do this than to dry it by the old methods, and the result is a very evenly distributed load. In Fig. 3 is shown a vertical section of the Lauffen station, and Fig. 6 shows the small size transformers used in Heilbronn for stepping down from 1,500 to 100 volts. The transformers are arranged in cast-iron boxes, in which are also placed the cable joints, the current indicators, and the fuses. The covers are made to rotate, and the cases form easily accessible junction and service-boxes. In Sontheim the transformers are on the roof of a building. The transmission wires are three in number, of 6mm. diameter, bare, and run on oil insulators supported by wooden posts; these latter being about 50 yards apart and varying from 25ft. to 50ft. high. The arrangement is shown in Fig. 4. The

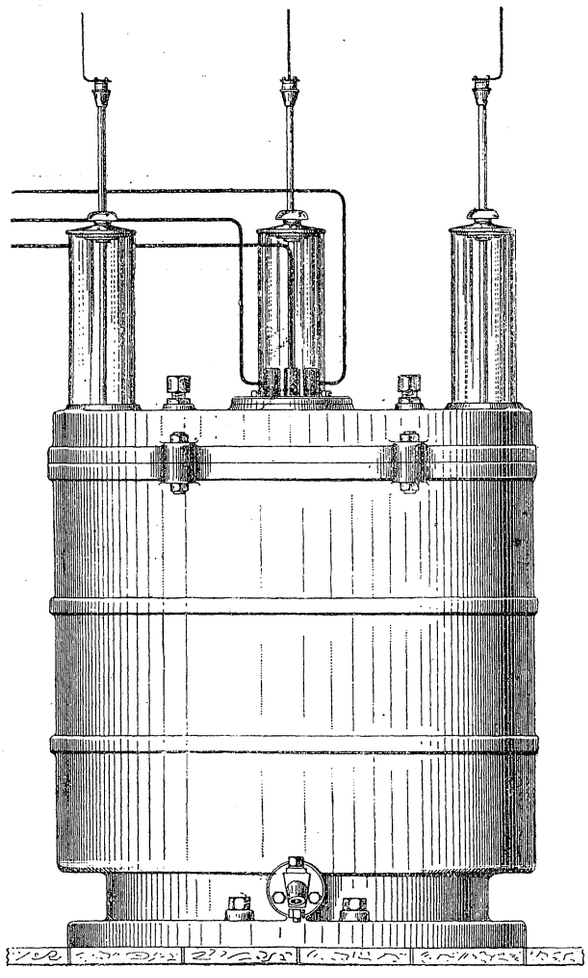

FIG. 6.—Heilbronn Step-Down Secondary Transformer. 1500—100 Volts.

wires are arranged on one horizontal line to keep them as high as possible above the trees; only three are at present in use. The posts are furnished with lightning conductors, connected to earth by barbed wire, which also serves to prevent climbing of the poles. About five miles of cables are laid, all of the triple-concentric type shown in Fig. 5. Every branch is furnished with fuses and safety apparatus. A feature of this transmission is the motors, which are extensively used. They are very simple, have no commutator, and are small for their output. To prevent the sudden variation of the light by switching in or out large motors, fluid resistances are so arranged that full contact can only be made after 15 or 20 seconds. Motors over 3 H.P. are coupled direct to the high-pressure network.

The price charged for lighting current is about 9d. per kilowatt hour, but if the current is used for motors or industrial purposes it is charged for at the rate of 4d. Reductions are made for long hours of working. The works cost up to March 1, 1892, about £13,000, and were then supplying 1,100 glow lamps of 16 c.p., 8 arc lamps (10 amperes), and 3 motors of 8 H.P. altogether. On November 1, 1892, the numbers had risen to 1,700 glow lamps, 20 arc lamps, and 11 motors of 32 H.P. altogether, and more were being daily coupled on. The public lighting of Sontheim takes 8 glow lamps of 20-c.p. Private consumers are also being coupled on in this village. The works have only necessitated adding three men to the number of the *employés* of the Portland Cement works.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 27th.

ROYAL UNITED SERVICE INSTITUTION.

3 p.m. Paper to be read: "Electric Balloon Signalling," by Eric S. Bruce.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "Japanese Magic Mirrors," by Prof. S. P. Thompson, F.R.S.; (2) "The Perception of Colour," by W. F. Stanley, F.G.S.; (3) "Recent Determinations of Molecular Refraction and Dispersion," by Dr. J. H. Gladstone, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "The Disposal of Town Refuse by Burning, and the Application of the Heat thereby Generated," by Arthur S. Butterworth, Stud.Inst.C.E.

SOCIETY OF ARTS.

8 p.m. Howard Lecture III. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Just Perceptible Difference," by Francis Galton, F.R.S.

MONDAY, January 30th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture II. (1) "The Practical Measurement of Alternating Electrical Currents," by Prof. J. A. Fleming, F.R.S.

TUESDAY, January 31st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read with a view to discussion:—(1) "Smelting Processes for the Extraction of Silver and Gold from their Ores," by Henry F. Collins, Assoc.M.Inst.C.E. (2) "The Erection of Silver-Lead Smelting Works in Mexico," by James W. Malcolmson, Wh.Sc.

WEDNESDAY, February 1st.

INSTITUTION OF CIVIL ENGINEERS.

2 p.m. Students' Visit to the North London Railway Works, Bow Road, E.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Purification of the Air Supply to Public Buildings and Dwellings," by William Key.

THURSDAY, February 2nd.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Annual General Meeting at the Institution of Civil Engineers. Election of Officers. Paper to be read: "Description of the Experimental Apparatus and Shaping Machine for Ship Models at the Admiralty Experiments Works, Haslar." by R. Edmund Froude.

FRIDAY, February 3rd.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. "Description of the Pumping Engines and Water-Softening Machinery at the Southampton Water Works," by William Matthews.

SOCIETY OF ARTS.

8 p.m. Howard Lecture IV. "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse:—"Theory and Practice in Electrical Science" (with experimental illustrations), by Alexander Siemens, M.Inst.C.E.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN,' *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.		6 months.		12 months.

LONDON COUNTY COUNCIL PATRONAGE OF TECHNICAL EDUCATION.

At length the report has appeared of the Committee appointed by the County Council to consider how to dispose of the sum of £180,000 a year, made available by Mr. GOSCHEN, under the Act of 1890, and also the detailed report of the Secretary. The latter is a folio volume of 183 pages, bound in brilliant scarlet. It contains seven maps, which are very pretty examples of chromo-lithography, but which do not add much to the elucidation of the subject. There are also illustrations of various institutions. For want of an appended scale, these views are very misleading as to the size of the buildings, for the proposed Chelsea Institute appears larger than the People's Palace, and the Battersea Polytechnic is represented almost as imposing as the City Guilds Institute, at South Kensington. The volume contains only a meagre table of contents and no index.

The secretary's report explains what technical education is, and distinguishes it from liberal education on the one hand, and from handicraft drill on the other. It utters the usual stereotyped condemnation of the French *école d'apprentissage*, and the usual stereotyped regret at the decay of the apprenticeship system. But it makes no suggestions as to any remedy. All this we have heard before. The report then gives a mass of information which if it had been properly tabulated would have been very valuable, and, even as it is, is very interesting. Unfortunately, however, but few of the columns of figures are added up, so that when the committee's report informs us that only 1,400 students in the Board Schools, and 18,600 in all other places put together, attend evening classes in any branch of science, art, or technology (of an industrial character), although the smallness of the figures may surprise

Hosted by Google

us, we have no means of verifying the assertion, nor of knowing what amount of study would be considered an "attendance."

The fact that 9,500 commercial students also attend lectures in the evening, does not seem to have been considered worth mentioning. From the figures in the table (which the reader must cast up for himself if he desires to know them), it appears that four Polytechnics have on the register about 8,000 evening students in scientific subjects, exclusive of commercial and other classes. This does not include the Borough-road Polytechnic, which, probably, has about 2,000 more. Of course, not all these attend regularly. So that it would seem as if of 20,000 evening students in science, art, and technology about one-third belong to the Polytechnics, 1,400 belong to the evening Board Schools, and the rest attend various classes either at voluntary institutions, or under the Science and Art Department. The number of people who are yearly under some form of evening instruction, whether industrial, or commercial, or literary, is probably about 40,000; but if it is recollected that about 100,000 children leave the Board Schools of London every year the small portion of those who continue their education becomes at once apparent. It is to be regretted that the report of the secretary gives us hardly any information as to the cost of the various classes which he mentions. Nor, again, does he give any comparison of the results—as, for instance, how many students from Polytechnic evening classes pass successful examinations, as compared with those from Board School evening classes. The subject is a delicate one, and comparisons are odious, so, possibly, it may have been thought wise to throw a decent veil over those interesting questions.

In their recommendations the Committee have had the wisdom to avoid one error. They do not intend to work any system themselves, nor to spend their money in bricks and mortar; they intend only to subsidise those institutions which already exist. For this purpose they propose that a Technical Education Board should be appointed, consisting of thirty-five members, of whom twenty are to be County Councillors, five from the London School Board, three from the City and Guilds Institute, and two from the City Parochial Charities. The Head Masters' Association and the National Union of Teachers are to have one representative each, and as it is of special importance that "the cordial co-operation of the Trades Unions should be secured" one place is given to a member from the London Trades Council. The co-operation, whether cordial or otherwise, of the employers of labour, or of the working men outside the favoured pale of the Trades Unions, does not seem to have been considered necessary. No special place is assigned to those who might be considered to be experts upon commercial education. Although in the secretary's report the efforts of the London Chamber of Commerce are rewarded with brief attention, it does not seem to have occurred to the committee that any benefit could result from the co-operation of that body. It is also curious that no provision should have been made for any representation of the Colleges of University rank upon the proposed Board. But there remain "other members not exceeding two," to be "selected by the Council from outside its own body.

The grants for the ensuing year, as recommended by the secretary and favourably received by the committee, are as follows:—To the Polytechnics, £16,000; to secondary day-schools (85 per cent. of the scholars of which are above the class of artisans), £22,000. It is proposed that this should be spent in a grant to secondary schools of £3 per head for all boys who have been in an elementary school, and in respect of whom the school-fee charged is not more than £3 a year. The fact of having been a public elementary school boy will soon become the only road to State pecuniary assistance; just as to attend church and take the Sacraments was once the only avenue to State employment. It would be advantageous if the grant was also given in respect of boys whose parents though once rich may have fallen into poverty on the same principles as the South Kensington grants extend to all boys whose parents have less than £200 a year. It is proposed that a grant of £3,800 should be given to University and King's and Bedford Colleges, to be increased to £10,000 a year as soon as the new university for London is formed and "adequate" representation is given to the London County Council, on its governing body. Of the remaining money, £8,000 a year is to be spent on scholarships, £10,000 is to be given to art teaching, £6,000 to science, £5,000 to technology, £3,200 to domestic economy, £2,000 to commercial subjects (which sum we hope will be increased in future), and £4,000 is to be spent in the formation of technical museums at Bethnal Green and in the Albert Palace, Battersea. The cost of administration is estimated at £5,000 a year, making a total of £85,000.

Taking the system as a whole, its principle seems to be to subsidise pretty fairly most existing institutions. The great danger will be lest the subsidies are not given as the result of patient and unostentatious work, but are left to the caprice of individual members of the Education Board, in which case electoral influences would be exercised and pretended privileges to the working classes paraded by various institutions in order to curry favour, as in the municipal schools in Paris. Far better will it be if some uniform conditions are imposed and the grants arranged upon some regular system, so that each institution will occupy itself seriously in doing good work, and not in cultivating "friends at court." Another danger would arise if the Trades Unions should attempt to capture the technical schools. Already in most of them certain trades classes are only open to them already in those trades. If this principle were too widely adopted the greatest injustice would be committed, as if, for instance, law were only to be taught to lawyers, or the teaching of medicine denied to all but doctors. In one case a whole class of plumber artisans refused to attend because a plumber's labourer was admitted. Even those most sympathetic with the objects of Trades Unions will hardly wish to deprive a labourer of his fair chance of becoming an artisan. To do this would be to convert a system of education into a system of the most odious class tyranny.

Upon the whole the County Council Committee is to be congratulated upon its recommendations. It has endeavoured pretty fairly to apportion the money at its disposal among the higher class education in which both rich and poor may participate, among the day schools chiefly used by the middle classes, and among those institutions more especially designed for workmen. This spirit of fairness augurs well for the future. Of course, no such system, however excellent, can cure all our ills. The true place to learn a trade is the workshop. Over-schooling has a tendency to produce priggishness in all classes. There are prigs in the Polytechnics as well as in the Universities. We are familiar with both specimens, but London is certainly deficient in secondary education at present, and if kept within reasonable limits and administered in a spirit of justice, the proposed subvention-system, with such modifications as further experience may suggest, will form an excellent basis for a scheme of municipal technical education, if, like everything else, technical education is to be municipalised.

NON-SYNCHRONOUS MOTOR FOR ORDINARY ALTERNATE CURRENTS.

BY C. E. L. BROWN.

After numerous experiments with multiphase motors, I had become convinced, about a year and a-half ago, of the possibility of constructing motors for ordinary alternate currents possessing all the characteristics which, till now, have been attainable only by the use of multiphase currents. Among these characteristics of multiphase motors I would specially call attention to the following :—

First and most important, absence of collectors and brushes, and consequent simplification of design and reduction in the amount of attendance necessary ; secondly, the possibility of starting the motor against a load ; and, thirdly, non-synchronous running with the various advantages connected therewith.

The absence of collectors has, in very many cases, the result that the multiphase motor must be considered preferable to the direct-current motor ; so that, without exaggeration, we may say that the alternate current (though not, it is true, in its simplest form) is considerably in advance of the direct-current as a means of driving motors. When we also consider the ease with which the alternate current may be transformed, we can understand how in all the newer power-distribution schemes the alternate current (of two or more phases) has been employed. A disadvantage is nevertheless soon apparent, to which too little attention was at first given, viz., the complication of the mains arising from the fact that more than two wires are necessary. This disadvantage is chiefly apparent in cases of combined distribution of light and power, and creates a demand for a motor for ordinary alternate currents of equal simplicity with the multiphase motors and possessing their various advantages.

Attempts have not been wanting to produce such motors. This is best seen by the large number of patent specifications filed, in hopes of attaining this end. I do not here propose to consider in detail those attempts, merely remarking that they have been all more or less unsatisfactory, none of them having, to my knowledge, been adopted in practice. The reason of these unfavourable results seems to be the same as, until recently, prevented the construction of practical multiphase motors. I refer, primarily, to the want of attention to the magnetic resistance of the air-gap ; owing to the abnormal magnetising current required, the windings, even while the motor was running light, became so warm that continuous running was out of the question. The efficiency was also, consequently, very low. I have, as is well known, by placing the wires in holes through the iron (both of the fixed and rotating parts), entirely overcome this difficulty, and thus produced the first really practical multiphase motor. Another defect was in the form of the magnetic circuit, with prominent poles which produced injurious reactions in the induced part, rendering the starting of the motor very difficult.

I would also call attention to another point, which is specially noteworthy in American practice, viz., the high frequencies commonly employed. This causes difficulties from the great counter E.M.F. of self-induction, as well as from the inconveniently high number of poles required on small motors, in order to avoid excessively high speeds. There are several other reasons why these earlier experimenters have failed ; but I have, I believe, enumerated above the most important.

After these preliminary remarks I will now proceed to describe my new motor, first noting the remarkable phenomena upon which the principle of it is based. I have observed that a conductor, placed in an alternating field, if set rotating with a certain velocity, will itself run up to practically synchronous speed, and then has the tendency to keep to this speed against a load. Currents are induced in the conductor by the alternating field. So long, however, as it is at rest, these currents are neutral with regard to the inducing field. As soon as the conductor is set in motion this condition ceases, and a turning moment is produced, which increases as the speed rises, till synchronism is nearly attained. The following points should here be noted :—With a conductor in the form of a solid disc, for example, the speed will drop more or less below synchronism, according to the load. With a deeply serrated conductor, on the other hand, or one consisting of but few members, the tendency is to preserve almost exactly synchronous rotation, and if the speed once falls much below this the torque is considerably reduced.

It must also be noted that the direction of rotation is quite indeterminate. The conductor tends always to attain synchronous rotation in the direction in which it was first set in motion. In designing a motor based on these facts, the following points must be kept in view. The alternating field must be as strong as possible, and all magnetic resistances (as well in the inducing as in the induced parts) must be reduced to a minimum. Injurious eddy currents in both iron and copper must also be avoided as much as possible. These various requirements can be satisfied in the following manner :—The inducing winding (*i.e.*, that in connection with the mains) as well as the induced (receiving its current by induction from the former) are provided with iron cores consisting preferably of iron discs insulated from one another.

In order to reduce the magnetic resistance, the windings are embedded in iron, either in holes of suitable shape or between teeth which may be advantageously closed by a winding of iron wire. The teeth may also be widened so as to nearly close the opening. Either inducing or induced parts may, of course, be provided with either of these arrangements.

The inducing winding may be, of course, of any of the usual forms, with a suitable number of poles, the sections being connected in series, parallel or in a combination of both. The induced, which is usually also the rotating part, since sliding contacts are thereby avoided, carries a short circuited winding preferably insulated from the core, in order to avoid eddy

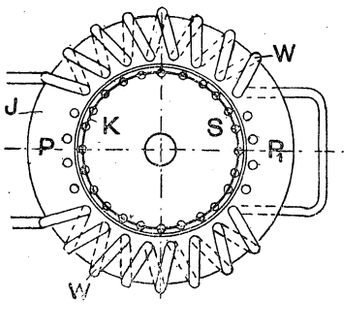

Fig. 1.

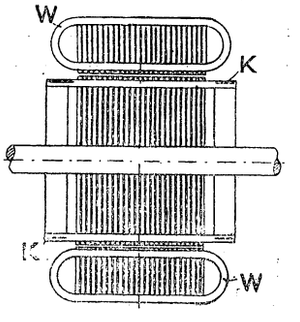

Fig. 2.

currents. This short circuiting may be carried out in various ways. All the ends at each side may be connected together by means of two copper rings, or the conductors may be connected in certain groups, which are separately short circuited. Or, again, wires similarly situated with regard to the external field may be separately short circuited with one another. Another method is to wind the induced part as ring, drum, &c., with a short circuiting connection. For regulating the speed a resistance, choking coil, or capacity may be inserted in the short circuit.

Figs. 1 and 2 serve to show the most important points about a motor designed on the above principles. The inductor J is shown fixed, and consists of a cylindrical core of laminated iron. The discs, of which it is built up, are perforated near their inner edges and carry the winding where shown as a ring (it could, of course, equally well be wound as a drum). The winding is not shown extending over the whole ring, but there is nothing to prevent its being so arranged. The connections are such, that poles are produced at P P.

The rotating part consists principally of a laminated iron cylinder carrying insulated copper wires S in holes close to its circumference. These wires are soldered at each end to stout copper rings K.

A somewhat different arrangement is shown in Figs. 3 and 4. This has the property, described at first, of almost synchronous running. Here, again, copper conductors S are bedded in a laminated iron core and soldered on both sides to stout copper rings K, the only difference being that the number of conductors is here very small.

Hosted by Google

Figs. 5 and 6 show another type of rotating induced part, provided with a ring winding S. The opposite points are here connected to sliding contact rings, so that a resistance for regulating the speed may be readily inserted.

A motor constructed according to the above principles and suitably proportioned has a remarkably high weight efficiency. I have designed a non-synchronous motor, for example, weighing only 150 kg., which at about 2,000 revolutions could be loaded to 6 H.P. without excessive heating. Its efficiency is very good and the apparent watts are but very slightly more than the true watts. The outside dimensions of the motor without pulley are :—Length (along shaft), 430mm. ; greatest height, 350mm. ; greatest breadth, 340mm. These figures suffice, I think, to show that the output of this form of motor is scarcely behind that of one for direct or multiphase currents.

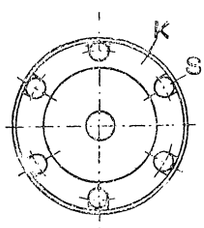

Fig. 3.

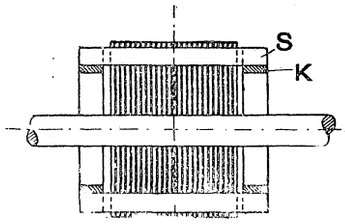

Fig. 4.

I may here briefly touch upon an important point, viz., the predetermination of the so-called "idle" or magnetising current, as it is, of course, necessary, in designing a motor, to be able to calculate this current. Experiments with a large number of motors of various outputs show that this may be done with sufficient accuracy for practical purposes, the observed currents differing in most cases by only a very small percentage from their calculated values. The same principles hold here as in the design of ordinary dynamo machines.

A convenient formula for determining the necessary values is that of Kapp (in his Paper on "Alternate-Current Machinery"). It is as follows :—

$$V = C \curvearrowright L W 10^{-8};$$

where

V = electromotive force.

C = a coefficient expressing the ratio between the E.M.F. of alternate and continuous-current machines. In the above-mentioned Paper will be found the values of C for various cases commonly occurring in practice. Herr Görges has extended this table giving values for other cases. (*Electrotechnische Zeitschrift*, 1892).

$\curvearrowright$ = total number of wires in the inducing part.

L = total number of lines per pole.

W = number of complete cycles per second.

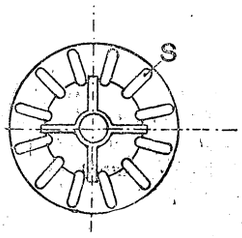

Fig. 5.

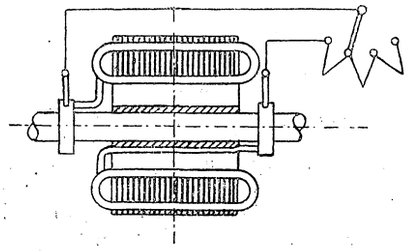

Fig. 6.

By substituting the values of V, C and W, we may find L the total induction and thence the density of the lines both in the fixed and rotating parts, as well as in the air-gap separating them. The mean length of the lines is taken at once from the drawing ; and from these data, by the well-known method of Hopkinson, the ampere turns necessary to produce this magnetisation can at once be found. The number of wires being given, we thus have the value of the idle or magnetising current.

Having found the current required to run the motor idle, we may easily determine with sufficient accuracy that required with a load. We may do this as with transformers having open magnetic circuits since in both cases the idle current lags 90deg. behind the working current. We have the following equation :—

Resultant current with any load = $\sqrt{I_i^2 + I_w^2}$.

There, I_i = idle current,

and I_w = working current.

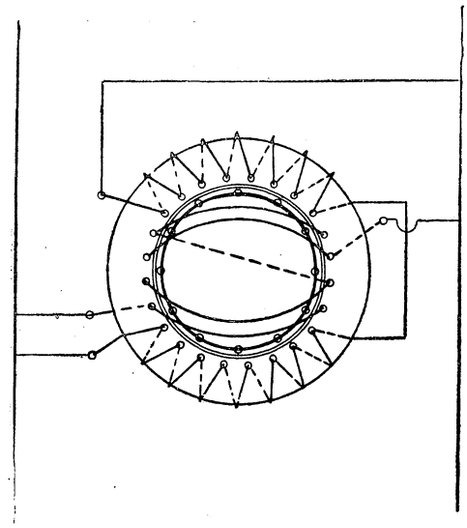

Fig. 7.

If for example, a motor takes 30 ampere idle current and 100 ampere current working, we have for the resultant current $I = \sqrt{30^2 + 100^2} = 105$ about—that is but a few per cent. more than the working current.

As regards induction in the iron, current density in the copper, &c., similar rules apply as for ordinary dynamo design.

As it would have occupied too much space to go at length into all the questions involved in the calculations for these motors, I have above merely sketched out the broad principles

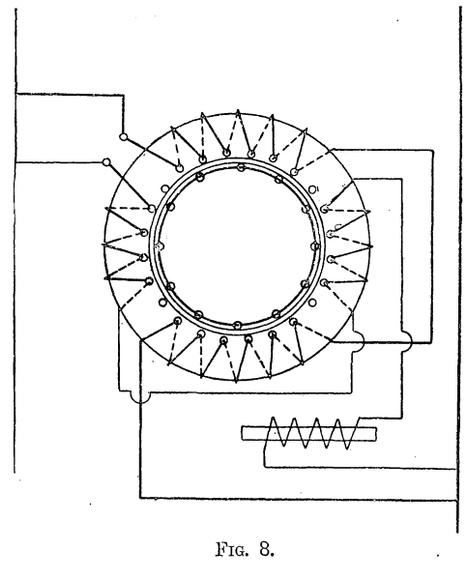

Fig. 8.

upon which they rest, wishing especially to point out that the calculations for such motors are similar to those which have long been in use for direct current machinery. I may add that what I have said above applies equally to multiphase motors, and, in fact, it should be clearly understood that with both broad types of motors the same principles apply throughout.

A motor designed in accordance with the principles described above has similar properties to a multiphase motor, *i.e.*, has no collector, runs non-synchronously, and, as far as efficiency and

Hosted by Google

output are concerned, is also very similar. In one respect only does it differ considerably from a multiphase motor, viz., it will not start itself, and some method must therefore be found of neutralising this disadvantage. There are various ways of doing this, of which I will describe a few.

The motor may, for example, be provided with a second winding, wound in the spaces of the first, and which, being only a short time in action, may be of relatively small section.

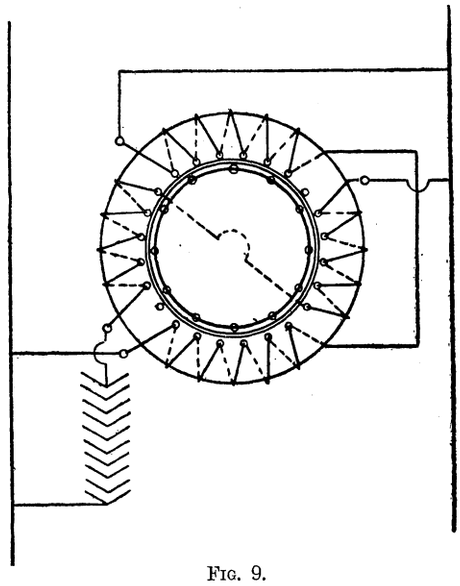

Fig. 9.

By giving this winding a different self-induction to the first, and connecting the two in parallel, the resulting phase-difference produces a rotating field, starting the motor and bringing it up towards synchronous running. This second winding can now be cut out, and the motor continues to run as single-phase motor as above described. The difference of phase in this second winding can be attained in various ways. One method is to wind one section as drum and the other as ring, as in Fig. 7, as it is well known that the latter has considerably greater self-induction than the former.

We may further attain the same end by connecting a self-induction (Fig. 8) or capacity (Fig. 9) or a resistance in

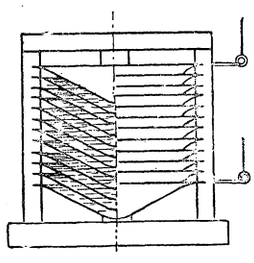

Fig. 10.

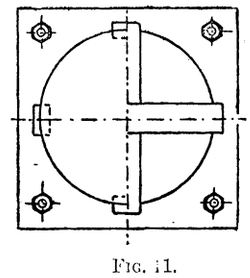

Fig. 11.

series with one section. This method may, of course, be used in conjunction with the above-described mixed winding. In order to obtain conveniently the necessary capacity, we may use a series of elements which Messrs. Stanley and Kelly have also lately employed in their experiments with alternate-current motors. A very convenient form of water capacity consists of a large number of iron discs dished out to a conical form, piled together with insulating distance pieces to allow room for the liquid. (*See* Figs. 10 and 11.) A solution of soda in water may be employed for filling. As a further method of obtaining the necessary difference of phase, suitably proportioned transformers may also be employed.

By means of this difference of phase, in a suitably-proportioned motor, a very considerable starting torque may be obtained. Thus I have succeeded in getting, with a 1–1½ H.P. motor, a torque corresponding to a load of 3 H.P. at full speed.

Another method of starting single-phase motors consists in providing the induced, usually the rotating, part with a winding connected with a collector (Figs. 12 and 13). By means of suitable brushes we may either supply this winding with current from outside, or the brushes may simply be short circuited. As soon as the latter are in their proper position with regard to the external field a powerful torque is produced, and the motor starts. As soon as sufficient speed is attained, the collector may be short-circuited by means of brushs pressing on contact rings connected with opposite points of the winding, or the winding may be short-circuited by means of a conducting ring brought into contact with the collector. The motor then works in the manner described above. In this case the inducting part is wound in the simple normal manner, *i.e.*, it requires no second winding, for the purpose of obtaining a difference of phase. On the other hand, the induced part has, instead of its simple short-circuited winding, a drum or ring winding, or it may be wound like the armatures of the Thomson-Houston or the Brush arc light machines.

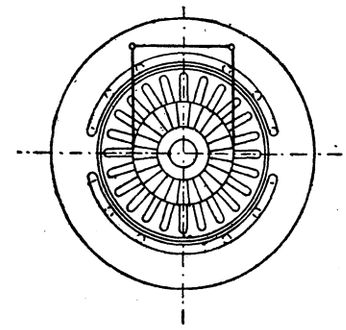

Fig. 12.

Having now described a few methods by means of which the motors may be started, I must not omit to say that those non-synchronous motors for ordinary alternate currents may be built of any size, from quite small types to machines of 100 H.P. and more. I believe that I shall not go too far when I say that in the above described simple motors we have a means of securing the speedy and certain extension of the use of ordinary alternate currents. These motors will be especially employed where light and power together must be supplied in the simplest manner possible.

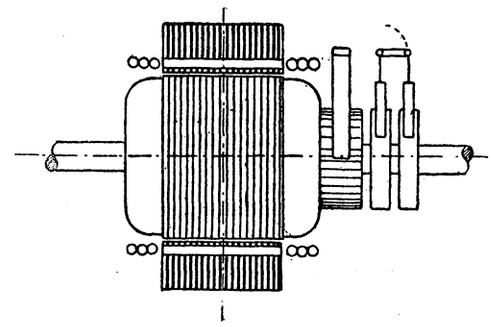

Fig. 13.

As regards amount of attendance necessary and safety in running, these motors are considerably in advance of those for direct currents, and as regards commercial efficiency for the same size, output, and speed are equally good. I am of the opinion that this new type of motor will displace multiphase motors in all those cases where, in addition to general lighting, power must be supplied, while for power distribution alone the multiphase motors will still find a use. In light and power distribution systems, having the so-called two-phase current, an advantageous combination of the two types of motor may be made. Thus small motors may be connected simply to one phase, like the lamps, while larger motors could be connected to both phases. I have now, I believe, described briefly the principal points of this type of motor; it is not yet possible to go further into details, especially as several questions with regard to patents are still to be settled. However, I hope that it will be possible before long to give a more particular description of some large installations employing this type of motor.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

In his last lecture he had explained that one essential condition to be met in arranging a central station was the fluctuation in the demand. He had shown at some length that this fluctuation involved, in steam-power generating stations which had no means of storage of energy, a great fuel consumption per horse-power hour supplied—a loss so great that in the very best-managed electric lighting stations the fuel consumption per horse-power hour was double the consumption required to do the same work at full load. Besides the cost of the fuel, there was a further item, namely, the interest and depreciation on plant, which was worked on the average for only one-third of the twenty-four hours. He had tried to show that that part of the fuel waste which was due to inefficiency of the engines at light loads could be accounted for, and to some extent that loss could be reduced by subdivision of the steam-engines into suitable units. The larger part of the waste, he was persuaded, in many electric lighting stations, must be attributed to the irregular working of the boilers. Storage would entirely overcome this difficulty. The secondary battery was so expensive that the solution of the problem was not to be found in that direction.

The Halpin Thermal Storage System.

The lecturer then went on to say that in his last lecture he had briefly explained a system which had been proposed by Mr. Druitt Halpin, a system in which for each pound of steam used 16lb. of water was heated to 406deg. at an absolute pressure of 265lb. per square inch, the water at the end of the operation being at a temperature of 367deg., ready to be heated to 406deg. again. Reference was then made to a diagram on the wall, which showed the general arrangement of a boiler and thermal storage tank on Mr. Halpin's plan. The boiler and the storage tank, which measures 30ft. by 8ft., were in free communication. There was an ordinary feed pump which supplied water direct to the boiler to make up for the waste in generating steam; but instead of keeping the water level in the boilers constant the water level in the storage tanks was kept constant, the boiler being filled with water. What happened then was this. The water was constantly being heated in the boiler and sent on into the storage tanks; in the storage tanks as steam was required it was given off, and the water there consequently fell in temperature; from the storage tanks the cooled water, together with feed, was constantly sent back to the boiler. The steam spaces of the storage tanks were all in communication, so that the pressure there was a uniform pressure in all the tanks. The steam required for working was taken off from the top of the storage tank through a reducing valve. If they had there a body of heated water, then any reduction of pressure at the reducing valve would cause the steam to go off at a rate depending on the difference of pressure. The storage tank was nowhere exposed like a boiler, and Mr. Halpin inferred that in that case it would not have any very rapid depreciation. What Mr. Halpin directly attacked by his device was the boiler waste and the difficulties of boiler management when the demand for steam varied from one-twentieth to four times the mean demand, a variation occurring every twenty-four hours. With thermal storage tanks the boilers could be worked continuously at a uniform rate throughout the twenty-four hours. The surplus heat in periods of small demand remained in the tanks, and the excess of steam demand over boiler production in hours of great demand was furnished by the storage tanks.

It was not possible to say without trial that no practical difficulties would arise in applying Mr. Halpin's plan, but he (the lecturer) had carefully examined the calculations, and had no doubt as to their accuracy with regard to the amount of heat stored and steam obtained, provided all things went on as Mr. Halpin supposed. He went one step further; so long as they had one boiler and one storage tank he thought everything would go on as Mr, Halpin supposed. When a new invention of apparent importance was presented the very worst attitude of mind with which to approach it was that in which you heaved a brick at it. He was not in the least likely to heave a brick at Mr. Halpin's system; at the same time, he would like thus far to qualify his statement. When instead of one boiler and one tank there were many boilers and many tanks, there did appear to him to arise some practical difficulties which did not appear yet to have been fully considered. There were difficulties of two kinds obvious on the surface, which he thought could probably be met. One was to obtain a sufficiently complete and rapid circulation, and the other was to ensure that when the pressure was reduced at the top of the storage tanks the steam was given off just where it was wanted, and not where it would embarrass.

* Abstract of Howard Lecture II., delivered before the Society of Arts, Friday, January 20th.

He thought the general method of working of Mr. Halpin's system was now clear, and he would, as it seemed to be really an important thing, now go a step further and examine what Mr. Halpin thought it would do in facilitating steam engine station working. Mr. Halpin had been good enough to put before him some figures which were based on a normal midwinter load-line of the Kensington electric lighting station. The total area of the load-line was 15,600 effective horse-power hours. The station could be worked, therefore, by engines and boilers which worked at 650 horse-power. Under present conditions, without storage, engines working to over 2,000 E.H.P. were required during the short period of maximum demand. Instead of boilers of 2,000 H.P. to meet the maximum demand, working on an average one-third of their time, and constantly shutting-off steam and then starting again, Mr. Halpin furnished boilers to supply a mean demand of 650 H.P., working them continuously during the twenty-four hours, and saving all the waste due to intermittent working. It was true that in place of the boilers dispensed with Mr. Halpin had to provide thermal storage tanks capable of supplying all the steam required when the demand exceeded the mean. An examination of the load curve showed that a store of steam amounting to 4,560 effective horse-power hours would meet the whole requirement. He found to store that amount of energy 900 tons of heated water were wanted, which might be contained in twenty-four storage tanks. Working the station *without* storage tanks, ten boilers were required, and the boiler plant would cost £10,300. Working the station *with* storage tanks three boilers were wanted, and 24 storage tanks. The storage tanks, on estimates which Mr. Halpin had shown him, and which appeared to be quite satisfactory, and the three boilers would come to £15,000. The cost of the plant with the storage tanks was, therefore, £5,000 more than the cost of the plant without storage tanks. But if they supposed that, in consequence of continuous working, only ½lb. of coal per horse-power per hour was saved, then the weight of coal saved would be 1,270 tons a year, and the value of that was a very good interest on the extra £5,000 spent on the plant. He did not doubt Mr. Halpin would put the saving at a great deal more than ½lb. per hour, and in stations they knew of it was inconceivable that there was not more than that which might be saved.

Cases which were still more advantageous, to the application of Mr. Halpin's system were those where there was now heat which was absolutely wasted. One such case was that of destructors for ashbin refuse. The destructor must be worked continuously day and night; it must also be worked at an almost regular rate, and the heat must be caught at the moment it was generated or lost altogether. It could hardly pay to attempt to use the heat from a destructor by any ordinary means, because the heat could not in most cases be utilised throughout the 24 hours. Another case which Mr. Halpin had thought of, and which was rather interesting, was this:—Scattered all over the country there were great manufactories of lighting gas; in those manufactories 312lb. of coke was burnt per ton of coal carbonised. For 312lb. of coke they would get 6,000lb. of furnace gas, which went off from the retort bank at a temperature of 1,200°F. Supposing the hot gases from the retort bank were taken through the flues of steam boilers of adequate heating surface, the furnace gases might be reduced in temperature to about 600deg. There was an available fall of temperature therefore of 600deg. in the furnace gases. That worked out to 759lb. of steam generated in the boilers by the waste heat of one ton of coal carbonised; that gave 25 E.H.P. hours per ton of coal carbonised. The gas industry was an enormous and wide-spread one. In the United Kingdom, there were 11,000,000 tons of coal carbonised annually for gas-making. The available part of the waste heat in the retort banks, at present all unutilised, amounted to 32,000 E.H.P. day and night throughout the year. That horse-power was equally available, of course, for electricity, compressed air, water, or any other form of power utilisation. Obviously Mr. Halpin's plan did very much facilitate any attempt to utilise waste heat of that kind.

Water-Power Generating Stations.

In the course of these lectures he had spoken of steam-generating central stations: he now came to the consideration of water-power generating stations. Where water-power could be utilised on a large scale, it was generally cheaper than steam-power. The water cost little or nothing, the cost of maintenance of machinery and superintendence was very small, the power was extremely regular, very controllable, and very convenient. The annual cost of water-power consisted chiefly of interest on capital expended in works and machinery. So well was this recognised that in industries like the aluminium industry, involving large quantities of energy, cheap water-power was considered the one essential of successful working. In this country water-power was unduly despised; in other countries water-power was hardly subsidiary to steam-power. The discovery of transmission of power to a distance made it possible to utilise water-power which was other-

Hosted by Google

wise unavailable. It was because such a transmission of power by new means seemed available that a remarkable interest had lately been developed in the question of using water-power. In Switzerland, he believed, 80,000 H.P. was derived from water-falls, and used for manufacturing purposes. It was estimated that the total water-power available in Switzerland was 582,000 H.P. Putting the value of a horse-power year at £6, this represented an annual value of £6,500,000, or 1,250,000 tons of coal. At this moment there was hardly an important factory in Switzerland which was not using water, making preparations for using it, or surveys with the view of using it. He now came to consider another country. It was in the United States of America that water-power was most largely used, and where it was in most direct competition with steam-power. The money value of the water-power utilised in the United States was very considerable ; in 1880, taking the value at only £5 per annum per horse-power, it was £6,000,000 ; taking the whole of the States, 36 per cent. of the power used in manufacturing was water-power. Over a considerable portion of the United States, especially in those parts which were the most populous and the most devoted to manufacture, the water-power exceeded the steam-power. The method in which water-power was utilised in America and distributed to a number of consumers was almost peculiar to that country. He would take one particular case, the case of Holyoke, which he saw about six months ago.

The whole of the factories in Holyoke were worked by water-power, and the system was strictly a distribution of power from a central station to many consumers at a fixed rate on the amount of power used. The first weir or dam was built in 1847, but was carried away ; a second dam of crib work was built in 1849, and in 1868 they constructed an apron to that dam ; since then very difficult repairs had been carried out, and he believed it would in time be necessary to replace it with a solid structure. From above the dam an intake canal led to what they might call the first level ; from that level the water was supplied to a number of mills, driving turbines, and passing out in the tail races and into level No. 2. Having got to level No. 2 it worked another series of mills by turbines in the mills, and from their tail races was discharged to level No. 3 ; and there were still other mills taking their water from level No. 3, and discharging their tail races into the river. The power utilised was 15,000 H.P. during the day and 8,000 at night. When the ground on which the mill was built was leased the right to use the water was leased with it. When Mr. Herschell became engineer to the Water Company, at a time when the dam had become ruinous and things generally were going to the bad, the use of the water at the mills was exceedingly extravagant. By introducing a system of testing the turbines, the use of the water had been enormously economised. The balance of water saved was sold as surplus power, and therefore the rental of the water-power had very greatly increased. There was a staff of three men at Holyoke, whose sole business in life was to walk round and note the level of the water in the head and tail races and the position of the sluices, two by day and one by night. A return was made to the office daily of the level of the water in every mill, and from that a curve was drawn of the consumption of water for every mill every day throughout the year, and on the area of that curve a charge was made to the mill for the water power it used. Mr. Herschell established a turbine testing station, the first in the world, to which turbines of any size might be sent. He saw tested in that house the first of the 1,500 horse-power turbines which were to be erected at Niagara. The cost of water power varied largely in different localities ; at St. Lawrence and Manchester the total annual cost of an effective horse-power was about £4. 7s. per annum. At Holyoke it was less. At Geneva it was under £3 per annum. He would like to say very generally that the cost of the effective horse-power derived from water in the manufacturing towns of the United States was certainly not over £3 per annum ; but there were cities where it was three or four or five times that. In New Jersey especially they were using a very large amount of water-power, which cost them three or four times that. Steam-power was not specially dear there, and the fact that in New Jersey they were using water-power where it apparently cost more than steam-power was pretty good proof that there were conveniences and advantages in many cases in the use of water-power which counterbalanced even an excessive cost.

Hydraulic Motors.

He would now say something about water-motors, water-wheels having been practically superseded. They might allow the water to descend in a closed chamber, and at the lowest point, to act upon the pressure engine, which had a piston just like a steam engine. There was another way of using water, which was to allow it to issue from a pipe under pressure, and to acquire velocity due to the head, and by then directing the water on to a turbine they would get a force which would drive the turbine. Pressure engines driven by water were generally cumbrous and expensive machines, but there were two applications where they were employed with advantage. For cranes or lifts, where slow motion was wanted, the direct action of water-pressure on pistons had been found to be extremely convenient. Small rotary motors, driven by water pressure, like rotary steam-engines, in a system of hydraulic power distribution where only an intermittent or small supply of power was required and a very great pressure was available, were also now very often used. The volume of water used by a pressure engine was constant whether much or little work was to be done. Pressure engines, therefore, although having an efficiency of 80 per cent. at full load, were very uneconomical for light loads. In Switzerland on systems of hydraulic distribution small pressure engines with two oscillating cylinders, the movement of which opened and closed the admission and exhaust ports, were very largely used. In Geneva they put a counter on small pressure engines, and the consumer was charged according to the number of revolutions the motors made. There was a pressure engine invented by Mr. Rigg, and possibly known to many present, with a variable stroke, in which the difficulty of varying the quantity of water used so that it was in proportion to the load was got over. Mr. Rigg's engine might have a uniform efficiency at all loads, and from its perfect balance it could run at very high speeds, but as the friction increased as the square of the velocity, its efficiency must fall with any great increase of speed. An engine of this type, with four cylinders, running at 90 revolutions at full load, at 110 at half-load, and at 130 when drawing empty waggons, was used in Wales.

For large powers the turbine was almost the only type of hydraulic motor used. The water was supplied from a supply-pipe and guided by fixed guide vanes, so that it entered the revolving wheel in a definite direction and at a definite speed. There were inward flow, axial flow and radial flow turbines. The whole principle was this : the water came from the fixed wheel and obtained a definite velocity and direction, and was then deviated by the curve of the floats of the revolving wheel. In consequence of this deviation it exerted a reaction on the wheel which drove the turbine. There was no essential difference between inward flow, outward flow, and axial flow turbines, choice depending upon considerations of secondary importance. A fundamental difference arose in turbines according to whether or not there was any pressure in the clearance spaces between the guide vanes and the wheel. In the older turbines the water left the guide vanes with only part of its pressure head converted into velocity head. There was then a pressure, greater or less, sometimes a pressure equal to half the head due to the fall at the point where the water entered the moving wheel. Turbines which had pressure in the clearance spaces were called pressure turbines. It was a condition of their use that the wheel passages should be completely filled with water. The velocity of the water in the wheel was determined by the section of the passages, and consequently the relative velocity of the water in the wheel increased during flow through the wheel. The other fundamental type of turbine, the impulse turbine, was one in which the water issued with the full velocity due to the head from the fixed guide vanes. There was no necessity in that case that the passages between the consecutive vanes of the moving wheel should be filled with water. As a matter of fact, not only was it generally not so, but ventilating holes were made which prevented any choking of the water in the passages of the moving wheel. The impulse turbine was so much more easily regulable that it was steadily gaining ground and displacing the pressure turbine.

The regulation of turbines presented a great deal of difficulty. Taking pressure turbines first, there were three modes of regulation. First, by an equilibrium sluice of some kind, placed in the supply pipe ; the head might be varied to suit the work to be done. As this mode acted by destroying part of the head or work of the water, it was very uneconomical ; and if the speed was to be kept constant it was worse still, because to each head there was a speed at which the turbine was most efficient, and if it had to be run at a constant speed it could not be suited to the different heads at which it had to act when a throttling regulation was used. That sort of regulation was very mechanical, very simple, very cheap, and very bad. A second way was one in which part of the passages in the fixed guide blades might be closed. In some turbines they shut up part of the wheel passages and left others open ; that was a very bad way of regulation. There was a great deal of eddying. There was a third mode. All the guide passages of a wheel might be simultaneously varied in area by some mechanical arrangement. If they supposed the whole of those fixed directing vanes moved so that the area might be simultaneously varied in all of them, then they would have a perfect mode of regulation for a pressure turbine. That had been done in some turbines, best of all in the turbine invented by Prof. James Thomson, and more or less in some American turbines.

He now came to consider the regulation of impulse turbines. In impulse turbines the water in the wheel passages flowed in a free stream. The closing of some of the guide-blade passages in the case of impulse turbines produced no appreciable effect on the efficiency.

Hosted by Google

The regulation of those turbines by partial admission was, therefore, easy and efficient. As every particle went into the wheel free to act for itself, it did not at all matter whether they closed some of the passages in the guide wheel or not. For high speeds a pressure turbine had an inconveniently high-speed of rotation; and the velocity of the wheel was a fixed function of the head, and the diameter of the wheel could not be much altered without seriously increasing the frictional or kinetic losses. Hence the number of rotations for a supply of water at a given head was fixed within very narrow limits in the case of pressure turbines. With a partial-admission turbine the diameter was arbitrary, and might be as great as they pleased. Hence the turbine could be designed to give any required number of rotations without its efficiency being in any way affected. To show how convenient impulse turbines were, he had placed on the wall drawings of some very large turbines at Greenock. Those turbines were of 580 H.P., driving rope pulleys and with regulation like those Geneva turbines. He also had drawings of a 800 H.P. turbine of exactly the same type used in the Terni Steel Works, where they drove all their machinery by water-power. One of the largest steam hammers in the world was there, worked by air compressed by water-power. A very curious type of the same kind had come into enormous vogue in the Western States of America. There was invented by a carpenter what was really a simple impulse turbine, which was known as the hurdy-gurdy or Pelton wheel. It consisted simply of buckets on a wheel; there was a jet of water coming through a nozzle and playing on those buckets, which were curved so that the deviation of the water was not very sensibly different from the other cases of impulse turbines. Really the Pelton wheel was a rather crude impulse turbine. He did not think it was quite as good as the Geneva turbines, but it had a very good efficiency; one at Holyoke, showing an efficiency of 80 per cent. under pretty high head. It was not at all suitable for a low fall. He mentioned it some time ago at the Civil Engineers, and since then Mr. Ellington had obtained two of those turbines and had placed them upon the London Hydraulic Company's supply system, and they were now working under a head equivalent to 1,600ft. head. Mr. Ellington assured him that they were both doing well, and had an efficiency of at least 75 per cent. In Washington Territory, quite on the Western coast, a very large electric lighting station was worked entirely by those Pelton wheels. He showed on the wall one mode of regulating the Pelton wheel; it was a very simple mode. There was an ordinary governor, and the governor tilted the nozzle. It was a very wasteful method; but where there was plenty of water that was not very important.

For a long time turbines were only used in cases where hand regulation was sufficient, and it was only since they had come to be used a good deal in connection with dynamos that the question of governing had assumed a very great importance. The regulation of water supply to a turbine was a very different thing from the control of the supply of steam to a steam engine. Turbine sluices were large and heavy in some cases, and required considerable power to move them. It was also necessary that all regulation should be gradual, because you had behind the turbine sluice a long column of very heavy water with a very large momentum, and if you tried to alter its velocity too suddenly destructive forces were called into action. It was not possible for an ordinary governor like a steam engine governor to act properly on a sluice except in small turbines. They must use a relay governor. There was a very curious action with a direct-acting governor. Suppose part of the load of the turbine to be thrown off, and the turbine to begin to gain in speed, the governor balls would rise, and as they rose they closed the sluice. That went on till the turbine ceased to gain in speed and began to fall in speed. As it fell in speed the balls fell again to their normal position, and as they fell reopened again the sluice a little way. With the clutch governor he had on the wall this action did not occur. Part of the load was thrown off, the balls rose, they put bevelled wheels into gear, so that the sluice began closing. The sluice began closing very gradually, and for some time the turbine went on gaining in speed, and got a great deal above its proper speed; but all that time the sluice was gradually closing. At last it closed enough to stop the gain of speed. Then the balls fell and threw the clutch out of action, and left the sluice too low down. The speed began to fall and the clutch was thrown out when the sluice was too low down. The reverse series of operations then began; the governor balls fell, the cluch, acting too gradually, opened too slowly, the turbine got much below its proper speed, the clutch re-opened and left the sluice too high up. With governors of that type they got a fluctuation of speed of this kind. There had been various attempts to get over that. Messrs. Rieter even used a friction break which was put into action by the governor and destroyed an excess of work at the time the sluice was getting into operation, and prevented the speed fluctuating as it did with an ordinary clutch governor. But the most beautiful turbine governors which he had seen were those which had been introduced chiefly in connection with the turbines round Geneva by Messrs. Faesch and Piccard. He had a diagram of one of their governors on the wall; they had several types more or less different, but this was a very simple one which was used on the 300 H.P. turbines which drove the dynamos for lighting Geneva. There were hydraulic cylinders with pistons of different areas. The under side of one piston was always under a constant water pressure due to the pressure in the water mains. The top side was usually in connection with the air, and had no pressure on it. By admitting water from the lower side of the lower piston, by admitting water through one passage and then through another passage to the top side of the larger piston, the ram moved downward. That was controlled by having a frictionless piston valve in the middle of the ram. This was put under the control of the governor, and as it rose the water was admitted to the top of the piston, and so caused the ram to move downwards and act on the sluice to close it. In the converse case, when the speed was falling, it placed the top of the ram in communication with the air, and so allowed the ram to rise and to open the sluice. If they studied that governor they would find two things: first that the action of the governor was almost absolutely unimpeded. There was almost absolutely nothing for that governor to do but think out whether the speed was right or wrong. The next thing was that there was only one possible position of the ram in which it was not moving, and that was just exactly where the speed was normal. It followed the action of the piston valve accurately.

CENTRAL STATION NOTES.*

BY W. BREW AND P. G. LEDGER.

The object of the authors of this Paper was to avoid as far as possible a mere record of tests and figures, and to select a few salient points from central station routine for discussion. They divided the subject into:—1, Boilers; 2, engines; 3, dynamos; 4, switchboards, instruments, &c.

The figures obtained by an expert's test as showing what can be done by care and attention to details are no doubt very valuable, and especially so to the man who wants to sell the engines, but the figures which chiefly interest the shareholders and managers of electric lighting stations are those giving the ordinary every day coal and water consumption and load efficiency under the working conditions of the central station. Tests during which more than the normal amount of care and attention was paid to firing and other details by the usual boiler and engine attendants are omitted, and the results of a few experiments made with plant in various places working under its normal conditions are recorded. At almost any central station in this country for a period of about two or three hours out of the twenty-four the load is twice or even three times the amount it is at any other part of the day. A good idea of about how much this affects the coal consumption may be obtained from the following experiment with four Lancashire boilers (18ft. in length by 6ft. 6in. in diameter, diameter of flues 2ft. 6in.), feeding the omnibus pipes at 80lb. steam pressure, from which three horizontal engines were supplied. The average consumption of coal per indicated horse-power hour was first noted starting and finishing with steam up and fires in normal condition, and was found to be about 4·31b., under the same conditions of load as would be applied when the effect of cooling down the boilers was taken into account. In making the second part of the test the *modus operandi* shown in the table below was followed. In the table one of the reference letters A B C D being omitted in the last column but one indicates that the corresponding boiler was allowed to cool down for that evening; to use the boilers equally a complete cycle of change would occupy four weeks.

Remarks.—Feed water supplied cold. Temperature about 55° F.

The above table shows that when specially steaming boilers for short periods of usage in an ordinary station routine, about double

* Abstract of a Paper read on January 20th before the Old Students' Association.

Hosted by Google

the price must be paid for an indicated horse-power hour compared with similar boilers continually employed for long intervals. This state of affairs could be improved by having previously at hand a fair supply of heated feed water; but in ordinary cases the supply is not sufficient to cope with the demand for extra boilers during the short interval of heavy load.

It is a well known fact that an over-compounded dynamo will not run satisfactorily as a generator supplying a shunt motor, if motor and generator be nearly the same size; a practical case of this was described by Mr. Kapp in *The Electrician* of April, 18, 1885, p. 472. Other facts equally certain, but perhaps not so well recognised, are that two over-compounded machines will not run satisfactorily in parallel, neither will two so-called compound dynamos, whose characteristics (terminal potential difference and current) deviate much from a straight line. These phenomena may be classed under two heads. 1st. Those due to the form of the characteristic of the machines concerned. 2nd. Those due to the effect of considerable self-induction coming into play with a rapid variation of the load as one or more of the machines are thrown in, with a consequent lag of magnetisation and potential difference at the terminals.

Fig. 1 represents the connections diagrammatically; s s^1 are the additional series turns, w a wire (usually called the balancing wire) joining the inside brushes *b b*, and A and B represent the omnibus bars. If we suppose the bars A B to have little or no resistance, or better, suppose the external circuit connected midway between the two machines, and add the resistance of one bar to each of the series turns of the dynamos, we find that the above connections reduce themselves to the well known lozenge-shaped diagram of the Wheatstone's bridge, the balancing wire replacing the galvanometer, as in Fig. 2. Let x y and z denote the currents in the various sections in the usual manner; then employing determinant analysis it may be shown that the current through the

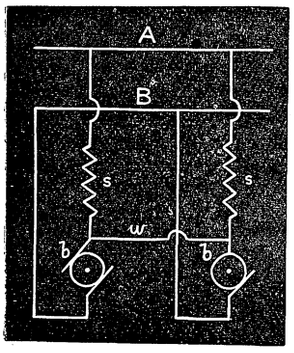

FIG. 1.

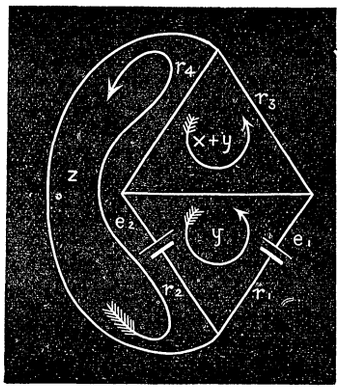

FIG. 2.

balancing wire will be proportional to the difference in the electromotive force of the two machines. Consider now the currents flowing in the series turns of the machines, *i.e.*, $(x+y)$ in the branch r_3 and $z-(x+y)$ in the branch r_4; denoting these by A and B respectively, and in the expressions putting $r_5=0$ we have :—

$$A=\frac{e_2\,(r_4\,r_1)+e_1\,(r_2\,r_4)}{\Delta},$$

$$\text{and } B=\frac{e_2\,(r_3\,r_1)+e_1\,(r_2\,r_3)}{\Delta},$$

from which it will be obvious that if in addition to r_5 being zero we have the condition $r_3=r_4$ then the currents through the series-turns will be equal; in other words, if the two machines running in parallel have equal resistance in their series-turns and the resistance of the balancing wire is small, then, whatever the difference between e_1 and e_2, or r_1 and r_2 may be, the currents through the series-turns of the machines will be nearly equal. The above simple investigation, therefore, shows us two things. First, that in order to run two compound machines in parallel efficiently they should be of the same size, or, at any rate, have equal resistance in their series-turns. Secondly, the balancing wire should be of low resistance and not a fine wire as is sometimes stated in text books.

Fig. 3 represents the characteristics of two compound dynamos which could not be got to run in parallel until the compounding had been altered; the speed of the machines had been altered to accommodate a greater drop of potential difference along the mains than was at first estimated for, owing to the replacing of several arc lamps by incandescent lamps on the mains. A glance at the upper part of the curves will show that the machines were over compounded at this speed, and it will be evident that two such dynamos working in parallel will be in a constant state of unstable equilibrium; for assuming the machines to have a load equally divided between them at the start, and anything to occur to alter this condition, such as the joint of a belt running over a pulley, or a slight variation in the speed of one of the engines if the dynamos are direct-driven, then that machine which has come off best with regard to the load has the potential difference at its terminals increased, while the reverse is the case with its neighbour, which rapidly relinquishes the remainder of its load to its stronger brother, and is promptly reversed, a proceeding which is generally accompanied by a pyrotechnic display at the commutators of both machines. Again, take the case of a somewhat common characteristic of a large compound machine in which the terminal potential difference rises until about half the load is on, then gradually falls until at full load it has exactly the same potential difference as on open circuit, it is obvious that two such machines running in parallel will also be in a state of unstable equilibrium for certain light loads. The practicability of running compound machines satisfactorily in parallel depends to a considerable extent upon the form of the characteristic of the machines concerned.

In December, 1890, in a letter to *The Electrician*, Vol. XXVI., p. 280, one of us gave some curves illustrating the lag of induction through the armature of a dynamo behind the magnetising current producing it, and as the curves refer to a machine similar in every respect to the two whose characteristics we have given in the last figure, it will, perhaps, make matters more complete if we give these curves again; we therefore reproduce them in Figs. 4, 5 and 6. Curves are first obtained showing the rise of potential difference at the machine terminals and the rise of current in the shunt respectively, with time after the closing of the shunt switch across the omnibus bars :—A com-

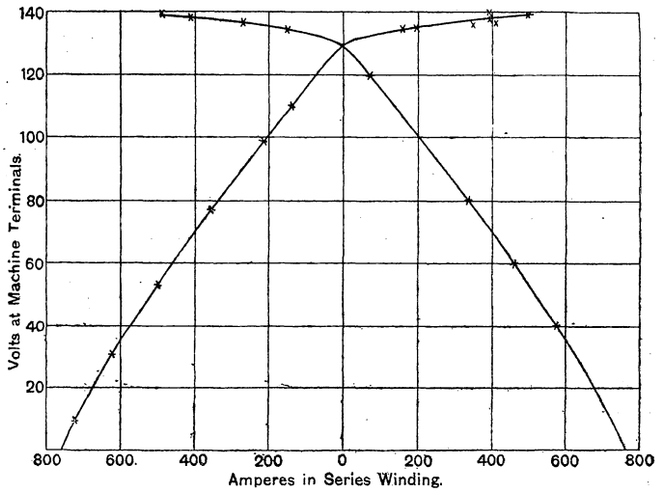

FIG. 3.—600 Revolutions per Minute. Total Ampere Turns 400 per Unit Division.

parison of the ordinates of these two curves at the same instant gives us a third curve which will represent to a certain scale the variation of the induction through the armature, with the exciting current producing it.

In Fig. 6 this curve, with varying current, is compared with a similar one taken with a steady magnetising current, a considerable interval being given between each reading to allow the magnetism to settle.

It will be obvious that, although the self-induction of the series turns may not be so great as that of the shunt winding, an effect of this nature will be of considerable importance in switching large compound machines rapidly into parallel. Suppose, for example, we have two machines, A and B, and we require to put A in parallel with B, which is loaded; and suppose we note the potential difference at the terminals of B, and make the electromotive force of A slightly greater (by altering the speed of the engine, or otherwise), so that A will take up some of B's load as soon as we close the switch, we see that B will behave as an over-compounded machine, and A the reverse for a short interval.

We have seen that we may express the final steady value of a current which will flow through a machine (when put in parallel and shortly after the switch is closed) in terms of its electro-motive force, and a certain effective resistance involving the resistances of the other machines already in parallel between the omnibus bars and the resistance of the external circuit.

In the ordinary state of affairs the shunt-circuit will be closed, of course, and a steady current will be flowing through it from the omnibus bars, and the only effect of importance upon this steady current when the main switch is closed will be that due to mutual induction between the shunt and the main circuit through the armature and series turns.

The usual way of regulating large shunt machines working in parallel, and coupled direct to the engine, is by varying the speed of the engine by means of an adjustable governor, increasing or

Hosted by Google

diminishing the tension of the spring according to the potential difference required at the machine terminals. An adjustable resistance in the shunt of the machine is sometimes used, but with a fair-sized dynamo this system of regulation is quite inadequate to cope with rapid variations in the load. In the case of a sudden load being thrown upon a machine direct driven, the speed of the engine may

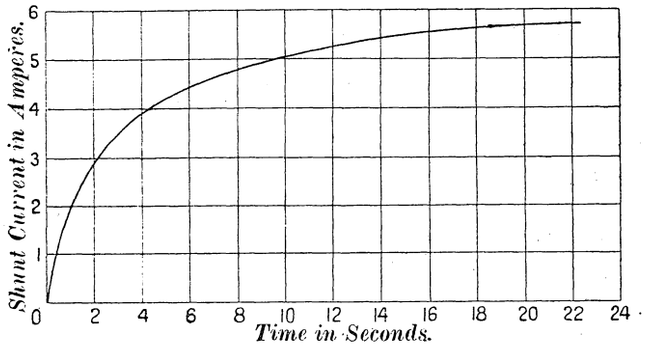

FIG. 4.

be raised quickly, and then lowered a little as the current rises in the shunt. In most cases, however, the loads thrown suddenly on the machine are not sufficient to cause any serious fall of potential difference, and the regulation may be, therefore, effected gradually. What occurs in an ordinary central station when

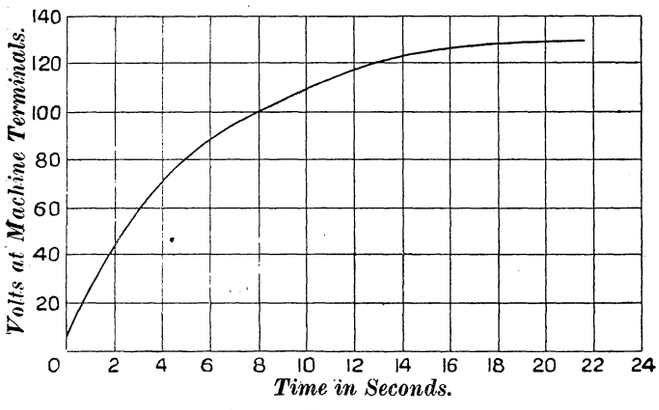

FIG. 5.

a sudden fog comes on is probably well known; a good deal more than the average amount of coal is burnt in the time, and a higher rate of activity generally is required of the staff. In the case of a station running with shunt machines direct coupled to their engines the number of dynamos connected to the omnibus

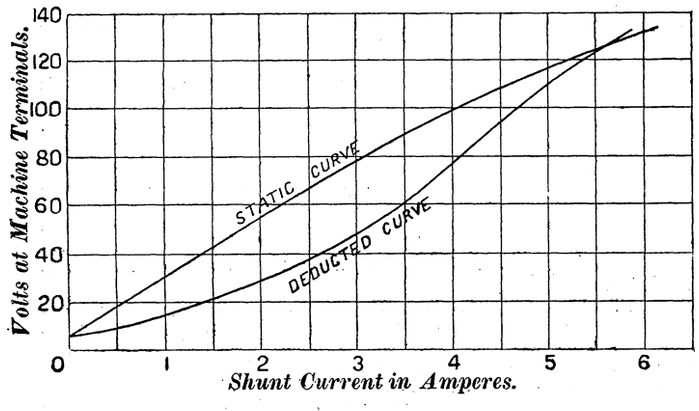

FIG. 6.

bars depends upon the demand of the customers at any time. In most stations of this type each dynamo is provided with an automatic cut-out placed between one or both of the machine terminals and the omnibus bars, whose duty it is to cut off automatically the machine in the event of a reduction in its electromotive force due to a hot bearing or other cause, thus saving the armature, whose electromotive force has been reduced, from destruction by the other machines coupled in parallel with it. Now, although an automatic "cut-out" may work with theoretical preciseness with an ordinary varying current, it is rash to rely upon it under the conditions of a sudden increment or decrement in the current passing through it, for, owing to the inertia of the moving parts (which must be made somewhat large to carry the current), many of those at present on the market will vary considerably in their point of cut off. Thus it happens that upon visiting some central stations, and examining closely some elaborate piece of mechanism of this nature, we discover a substantial wooden wedge, or piece of stout whipcord to be necessary to the satisfaction of the engineer in charge, rendering the ingenious and admired apparatus quite passive as regards either service or mischief. When full-sized motors are coupled to the mains they do not tend to improve the steadiness of the light, for their load is constantly varying with uncertainty, and although helping to keep up the all-day efficiency of the plant, matters would be improved if they could be run off mains distinct from the lighting mains. Some kinds of electric lighting also, such as that of theatres, often require for stage effects, &c., rapid and considerable variations of current, but the redeeming feature of theatre lighting from a supply station is that the station people know within a minute or so when the load will vary, and the amount of its variation, and are therefore on the look out for it. The late Royal English Opera House, although coupled to the mains of the Metropolitan Electric Supply, was ordinarily worked from its own installation under the management of Mr. J. Peschek. The conditions of the working were somewhat trying; for instance, the great necessity of crispness in response to signals, and the manipulation of large and varying loads thrown suddenly upon, and again taken as rapidly off, the keeping of boilers under steam for several hours for the special requirements of, perhaps, an hour or so, &c., &c. The installation comprises three locomotive boilers (by Marshalls), supplying with steam three Willans compound engines coupled direct to Siemens shunt dynamos, having an output of 650 amperes each at 100 volts. A set of 108 E.P.S. 31 L accumulators are also used for supplying light during the day throughout the house; these are charged in three sets parallel and discharged in two sets parallel. The current leaving the engine-room during an opera usually varied from 600 to 1,200 amperes, and the total consumption from 300—550 B.T.U. per diem. The following items compose the cost of running the installation per diem with seven performances per week, two performances usually being given on Saturday, and about three full rehearsals in a month, the results being the average of some months' running:—

Engine-room wages	£1	19	0
Depreciation of plant at 10 per cent.	5	0	0
Water for boilers	0	2	0
Fuel " "	2	2	0
Repairs, oil, and waste	0	11	0
Total	£7	14	0

Taking the case of the operas *Ivanhoe* and the *Basoche*, with an average consumption of 459·37 B.T.U. and 524·25 B.T.U. respectively, we find the cost of production per B.T.U. during *Ivanhoe* was 4·02d., and during the *Basoche* 3·52d., which, when we consider the size of the plant and the trying load curve, is not at all bad.

NON-POLARISED AMMETERS.

I desire to call attention, says Mr. Clarence E. Gifford in the *Electrical World*, to the danger accompanying the use of non-polarised ammeters in power stations. The danger lies in the fact that instruments of the non-polarised type give always deflections in the same direction, regardless of the direction of the current. Take the case of two or more shunt or compound wound machines working in multiple. Suppose that the voltage of any machine of a group falls, from any cause, to such a point that the output from that machine is nil, the index of the ammeter falls back to zero. If this escapes the notice of the attendant the pressure from this machine may in another moment have fallen to such a point that the machine is receiving current and running as a motor. Even the provision of equalising wires, where these compound dynamos are worked in multiple, does not, unless the equalising wires are of exceedingly low resistance, entirely obviate the evil effects of the series winding on a compound dynamo that once decides to start in business as a motor. In other words, so long as a dynamo is producing ever so small an output (whatever the output of its companions), just so long the series windings, working in connection with the equalising wires, will operate in their legitimate manner, and tend toward effecting a uniform voltage in the various machines of the group. But when the output of one of our machines gives

Hosted by Google

place to an income of current, the income of the owners of the plant is sometimes affected in an inverse ratio.

Returning after this digression to the point where one of our dynamos became a motor. Its ammeter leaves the zero point and indicates an amount of current which the attendant innocently supposes to be output. This may soon give a reading exceeding the output of any single one of its companions. The attendant "regulates" the machine by throwing the resistance into the shunt field; the ammeter, somewhat to his surprise, goes farther ahead of its fellows; he regulates some more, and the ammeter takes another jump; he gets excited, and there follows a race between him and the wheel of the rheostat on the one hand and the ammeter on the other; and, before the range of the rheostat is reached, the engine joins in the chase, because its dynamo is now operating with such power as a motor that the engine will be pulled through at a high speed, her governor being simply capable of limiting the steam supply within certain limits, but beyond such limits being of no avail in counterbalancing the power of the motor. Meanwhile, suppose, in addition to your "self-imposed" burden, that a heavy line load has come on—Results: blown fuses, overloaded dynamos, lines shut down, new fuses, and new and probably fruitless attempts to regulate—Bedlam in the station, and the "devil to pay" generally. Query: Why didn't you apply your voltmeter to the troublesome machine? Well, personally, I never had the above sad experience, but any one who knows the ordinary ways of a power station will be able to answer the question, and will also be readily able to see how a combination of high ammeter, low voltmeter, and run away engine might be a somewhat difficult problem for a man of even good ability.

Remedy: If you use non-polarised ammeters for your machines, put a brass strip across the front of the case, near the top, and from the centre of this strip pivot a vertical polarised steel bar or needle, the pivot being slightly above the centre of gravity of the needle. The needle should be of good magnet steel, well charged, and so pivoted as to move very easily. Then, if the current passes in the same direction through all your ammeters when the machines are in proper operation, the polarised needles will, of course, all be deflected in the same direction, one with another; and any deflection to the opposite side of the vertical line will indicate that the dynamo to which it belongs is being run as a motor.

THE ELECTRICITY SUPPLY BUSINESS IN PARIS.

The following table deduced from one published by *l'Industrie Electrique*, may prove of interest when compared with similar ones relating to the metropolis. The total lampage of these four companies amounts, it will be seen, to 170,000, yielding a total income of £240,000, or an average of £1. 8s. per lamp:—

Company.	Capital £	1892. Receipts £	10 c.p. lamps connected.	Capital £ expended per lamp connect'd	Receipts £ per lamp connected.	Length of mains (miles).	Lamps per mile of main.
Edison ...	200,000	80,000	45,000	4·44	1·7	20	2,250
Clichy ...	200,000	40,000	30,000	6·67	1·3	22	1,370
Popp	440,000	40,000	50,000	8·80	0·8	51	980
Parisienne.	400,000	80,000	45,000	8·88	1·7	20	2,250

PHYSICAL SOCIETY.

At an ordinary meeting of this Society, held January 13, 1893, Prof. G. F. Fitzgerald, M.A., F.R.S., President, in the chair, a Paper was read by Mr. F. W. SANDERSON on

"Science Teaching."

In this communication the author considers the methods of teaching physical science, and remarks that other sciences may best be treated in some different manner. The method recommended is one found suitable in public schools where boys may remain till about the age of nineteen In elementary and secondary schools modification would be necessary with a view to making it more immediately useful, whilst in university and technical colleges other methods might be preferable. The object of his public school method was to make physical science a definite means of education, rather than to produce skilled physicists. Certain mathematical subjects, such as arithmetic, geometry, and algebra, should be taught before physics is begun, and taught in such a way as to aid subsequent physical work. In teaching arithmetic it is deemed desirable to distinguish between the science and the art of it, and to have separate hours for instruction in each. The subjects included in each part are described in some detail in the Paper. No existing arithmetic satisfies the author's requirements. Geometry is considered of the first importance; practical geometry and the use of instruments forming the best introduction to the subject. It is recommended that the elementary part be taught by the mathematical master with a view to formal geometry, *e.g.*, Euclid. As most practical geometries consist of isolated constructions they are useless for teaching the subject in a scientific manner. Number of problems suitable for a graduated introductory course are given. After elementary geometry mensuration may be taken up with advantage, the facts being verified by drawing to a scale, measuring, or by weighing, but no rules being given. Trigonometry of one angle may then be commenced. Here also free use should be made of the drawing board, each pupil finding the sines, cosines, and tangents of angles by drawing and measurement, and making tables. Quite independent of the mathematical class, the author has been in the habit of carrying boys on the engineering side through a course of graphical analytical geometry, in which they draw straight lines and the quadratic curves, &c., from their equations, solve simultaneous linear equations, quadratics, cubics, &c. Other geometrical constructions follow. The subject as to what branches of science should be taught in the different departments of a school is then considered, and schemes are given for the Classical, Modern and Commercial, Science, and Engineering sides. Some general principles which have been kept in view in arranging the physical teaching are next described. In the first place the fundamental experiments and observations on which each scientific law is based are explained to the pupils, and when possible the experiments are performed by the boys in the laboratory. Secondly, from the experiments the laws are stated as precisely as possible, the form of statement depending on the knowledge possessed by the class. The problem of expressing a law mathematically from its most fundamental statement is then fully considered. Thirdly, mathematical deductions from the laws are followed out, and the pupils perform experiments to verify the results, and thus confirm the laws. Fourthly, a course of exact physical measurements is given, which includes mensuration, hydrostatics, mechanics, sound, heat, electricity and light. A first and second year course is arranged in each subject, and in both years all the boys work the same experiment at the same time. This necessitates multiplication of apparatus, but being of a simple character in the lower forms, where the pupils are numerous, it is not prohibitive. It is also stated that boys get better results with comparatively rough apparatus, if large, than with delicate and expensive instruments. About half the time devoted to physics is spent in the laboratory. Mathematics is introduced as far as can be done without straining the pupils too much, and with young classes appeal is made to experiment where the strictly logical argument would be difficult to follow. Instead of teaching the applications of science, as done in some technical schools, the author's method is to teach pure science, and let the applications come in as illustrations.

At the end of the Paper detailed lists of experiments for practical courses in electricity and optics are given. Samples of the apparatus used were exhibited at the meeting, those for optics being particularly simple and ingenious.

DISCUSSION.

Prof. A. M. WORTHINGTON said his experience led him to a very hearty agreement with Mr. Sanderson on all essential points, and he thought there was now a close agreement amongst teachers as to the best methods. He therefore wished to ask: Had not the time now come at which the Physical Society might usefully endeavour to exert direct influence on science teaching? As the scientific instruction of a person who intends following a scientific calling is generally divided into stages, and conducted in different places under different teachers, he thought it was desirable that those in charge of his training at each stage should say up to what point his instruction should be carried before he reaches them. Other matters in which the society might do useful work were, 1st, reporting on text books and condemning the bad ones, and 2nd, furthering the adoption of the decimal system. At present, he said, an enormous extension in the teaching of physical science is taking place, and it seemed within the power of the Physical Society to place itself at the head of the movement. Another point which required to be settled was the relative importance of physics and chemistry at different stages of a student's education.

Mr. L. CUMMING agreed with the general principles laid down by Mr. Sanderson. In attempting to carry out such schemes numerous difficulties presented themselves, especially where the science master had not control over the subdivision of the boys' time. He had tried teaching the science of arithmetic to boys in the lower forms, but the results were not encouraging, for he found very few who could do much in it. They seemed to devote themselves much more readily to concrete problems and the art of manipulation of rules. Graphical statics was very valuable. As regards experimental lectures, he believed them to be very important, especially in junior classes. For scholarship boys, a different method had been tried with success. Instead of performing lengthy experiments completely before the class, the essential parts were gone over, and for the minor points the results obtained in experiments made before or after the lecture were given, so that all the data for reducing the results were to hand. This saved considerable time. He had hoped Mr. Sanderson would

Hosted by Google

say something about the slide rules, and wished to learn his opinions on its use.

Dr. STONEY said he was very much struck with the methods of teaching brought forward by Mr. Sanderson, and remarked that his own work would have been considerably lightened if such a scheme had been developed many years ago. Experimental methods were very valuable, provided the inaccuracies of measurement be kept in view. Plotting curves was also very instructive, and might be made a means of furnishing the fundamental notions in the differential and integral calculus. As to the introduction of chemistry, his experience went to show that this should be done at an early age. Dynamics should also be begun early.

Mr. W. B. CROFT thought that if the Society did make rules to regulate the teaching of physical science, these rules should not be too strict, for the ages and aims of boys might differ widely. At Winchester the science teaching was carried out on the lines recommended by a committee of the Royal Society appointed to consider the subject. The object of the scheme was not merely to make science a means of education, but an integral part of the education of the pupils. He also made a point of keeping the lecture experiments up to date.

Mr. RENTOUL said dynamics should not be taught as a mathematical subject, but experimentally. He thought it of the first importance that boys should learn how to find out facts for themselves, and for this practical work was essential.

Prof. AYRTON remarked that the conditions under which science was taught differed in different places. He himself taught with the object of enabling the persons under instruction to improve the industry. For this purpose he believed the analytical method more suitable than the synthetical one advocated by Mr. Sanderson. It also had the advantage of being more scientific, for it was more natural, being in fact that used by children from birth, for they had no other means of learning the nature and properties of their surroundings. In his first year's technical course the work was synthetical, whilst in the third year the students, having analysed existing apparatus, were taught to devise new or improved forms, and hence the work became more synthetical.

Mr. F. J. SMITH said it was important that students be taught to measure by the balance, micrometer, spherometer, &c., as soon as possible. He also inquired how far Mr. Sanderson's pupils could help themselves in making the apparatus required for the simple experiments.

Dr. GLADSTONE agreed with many points in the Paper. Lately he had had to do with schemes for improving the teaching in elementary schools. Children were naturally philosophers, but at present their curiosity was considered objectionable and sternly repressed. Efforts were now being made to alter this state of things. Kindergarten classes in infant schools were a step in the right direction. It was very difficult to introduce analogous methods in the higher standards, but natural science had now obtained a footing. Although the methods of teaching adopted might be those suitable for pure science, care should be taken to put in practical illustrations, for when suitably chosen, they are sources of great interest to children.

Mr. SANDERSON, in reply, said the slide rule was used throughout the course. Mechanics was taught by actual machines, such as pulley-blocks, screw jacks, &c. The boys made some apparatus, but to make all would require too much time.

The PRESIDENT, when proposing a vote of thanks to the author of the Paper, said that in Ireland the opinion that boys and girls cannot be taught science greatly predominated. They found considerable difficulty in getting any continuation of kindergarten teaching sanctioned. Possibly drawing might be allowed, but this seemed all they could hope for at present. He wished to emphasise the fact that in such schools the object was education, and practical applications of science were not important, except in so far as they created an interest in the subjects. At present scientific teaching was in an experimental stage, and, as in other things, progress is made by trial and error. Many different methods were being tried, and it was important to know which were successful and which failures. He thought the Physical Society might be useful in collecting information on the subject by issuing a circular of questions to science teachers, and subsequently drawing up a report on the subject.

LEGAL INTELLIGENCE.

The National Telephone Company (Limited) and Another v. Graff Baker.

TUESDAY, JANUARY 17TH.

At the opening of the 6th and last day of this case Mr. BOUSFIELD stated that the Solicitor-General was unable to resume his argument, and proceeded himself to take up the citation of American cases.

Mr. BOUSFIELD said he would only trouble his Lordship with one case, an important one, in which the British authorities were cited, and which plainly went on the same law as was administered in his Lordship's Court. It was *The Cumberland Telephone and Telegraph Company* v. *The United Electric Railway* (42 Federal Reporter, p. 273). The concluding passage of the judgment in this action ran as follows:—"The substance of all cases we have met with in our examination of this question—and we have cited but a small fraction of them—is that, where a person is making lawful use of his own property, or of a public franchise, in such a manner as to occasion injury to another, the question of his liability will depend upon the fact whether he has made use of the means which, in the progress of science and improvement, have been shown by experience to be the best; but he is not bound to experiment with recent inventions not generally known, or to adopt expensive devices when it lies in the power of the person injured to make use himself of an effective and inexpensive method of prevention. If in the case under consideration it were shown that the double trolley would obviate the injury to complainant without exposing defendants or the public to any great inconvenience or a large expense, we think it would be their duty to make use of it, and should have no doubt of our power to aid the complainant by an injunction; but, as the proofs show that a more effectual and less objectionable and expensive remedy is open to the complainant, we think the obligation is upon the Telephone Company to adopt it, and that defendants are not bound to indemnify it; in other words, that the damage incidentally done to the complainant is not such as is justly chargeable to the defendants. Unless we are to hold that the Telephone Company has a monopoly of the use of the earth, and of all the earth within the city of Nashville, for its feeble current, not only as against the defendants, but as against all forms of electrical energy which, in the progress of science and invention, may hereafter require its use, we do not see how this Bill can be maintained. We place our denial of an injunction on the grounds: Firstly, that the defendants are making lawful use of the franchise conferred upon them by the State, in a manner contemplated by the statute, and that such act cannot be considered as a nuisance in itself. Secondly, that in the exercise of such franchise, no negligence has been shown, and no wanton or unnecessary disregard of the rights of the complainant. Thirdly, that the damages occasioned to the complainant are not the direct consequence of the construction of the defendant's roads, but are incidental damages resulting from their operation, and are not recoverable. The cases involving this principle are almost innumerable, and in our examination of them we are satisfied the great weight of authority bears in the direction we have indicated. As a result the motion for an injunction must be denied." The learned counsel then commented on the cases quoted by Sir Richard Webster in his opening speech. The defendant rested his case on the well-known case referred to of *Vaughan* v. *the Taff Vale Railway Company*. He submitted that the present case was almost identical with *Vaughan* v. *the Taff Vale Railway Company*. That was a case of what might be called dangerous employment of a dangerous article, a locomotive, and it was upon the ground that the statute had expressly authorised the use of a dangerous article, and that the dangers of the article were contemplated in authorising its use, that it was held that the result, namely, the sparks setting fire to some of the property, was one contemplated, and one against which the defendant was protected. Assuming, of course, that the danger here from an electric railway in reference to the present case was a danger simply of disturbing somebody else's wires, that was the danger which the use of electricity involved. He submitted that as the net result of the evidence the plaintiffs had failed to discharge the burden which was upon them, of showing that his client had been guilty of any negligence in the adoption of the system actually adopted. If disturbance of the kind complained of was a nuisance, then a disturbance by a telegraph wire, either so long or so near as to affect, or even a telephone wire which was so close as to affect, would also be of the same character. Therefore the plaintiffs' argument necessarily led to the result that any electrical disturbance which was so great as to make noises upon their telephone wires was a disturbance which was *per se* a nuisance, and which was actionable. On the other hand, what the defendant submitted was that these were disturbances which were necessarily incidental to every great city, to every place such as Leeds or London, and that having regard to the quantity of telegraph, electric light, electric power, electric tramway wires, and so on, that were gradually being used for different purposes, electrical disturbances were things which were incidents in the present state of civilisation, even though they were not incidents ten years ago, when the telephone was established, and that they were disturbances which the telephone companies themselves could, and ought, and must, from the very nature of their business, protect themselves against. Supposing the plaintiffs were freeholders, and that he was a freeholder, and that between the lands there was a long boundary. On the boundary of his land he put up a telegraph wire of sufficient length; on the boundary of their land they put up a telephone wire coming within the range of disturbance. Then they would be entitled, if Sir Richard Webster's law was good law, to complain of the use of the telegraph wire as a nuisance if there were electrical disturbances. His case was that these were disturbances which, in a crowded place and in cities, people who had a business depending on very delicate currents must necessarily contemplate, and that they could and ought to protect themselves against these disturbances from the very nature of their business, and from the nature of the requirements of mankind at large in regard to other electrical devices which were now coming into common use. If they looked at the New Telephone Company and the Post Office they would see they acknowledged that it was an incident of their business that they must protect themselves against the ordinary incidents of that business. All over the world, practically, other people were doing the same thing. In New York they were transforming the exchanges, and abandoning earth returns. In Stockholm, even, where there were 10,000 telephones, which was a great number for a place of that size, they were already transforming their exchanges. In other places, for instance, in Paris, they had already transformed the exchange. The plaintiffs apparently still stuck, whether from motives of economy or in order that that list of dividends which his Lordship had before him should be kept up to its high water mark, to the old "cheap and nasty" system of the earth return.

Sir RICHARD WEBSTER, in his reply, said he hoped that he could render his Lordship some assistance in deciding a very interesting case, involving novel considerations. With regard to the Solicitor-General's ingenious water well analogy, he had at once to point out that the facts proved in evidence showed that no such analogy existed at all. What was the defendant doing? Was he drawing from the reservoir of the earth, putting down a pipe, and getting up natural water? No, he worked steam engines, he worked dynamos, and generated vast currents of electricity, not existing in the natural and uninterrupted condition of the earth. The defendant established a non-natural condition of things. A person who unlawfully for his own purpose created a non-natural state of things, who brought on his property a wild beast, did it at his peril.

Hosted by Google

His clients stood in the position that what they were lawfully doing was hurting nobody else; what the defendant was lawfully doing was injuring individuals who were carrying on a lawful trade. Since Mr. Macrory's report there was no dispute as to a damaging escape of electricity. According to Prof. Silvanus Thompson's evidence prior to 1880, the maximum electrical energy employed was about one-sixth of a watt. The defendant's dynamos developed 60,000 watts; 360,000 times as much energy. Was not that the keeping of a wild beast, the escape of which must be guarded against and prevented by those who, for their own purposes, had thought fit to utilise that extreme power. A somewhat curious and far-fetched argument was used that morning. It was said that there must have been contemplated electricity which would do harm to neighbours because there was a clause which especially protected the telegraphs. A person must have had very little experience of the passing of private Bills through Committee to use any such argument in a Court of Justice. One had only to read the language of the section relating to the telegraph wires in order to come to the conclusion that it was an incorporation of a special code for the special protection of Government property, no private individual being in the same position. Private individuals were left to assert their rights in the Courts in the way they were doing that day. Coming to the American cases, he would cite the judgment of the Supreme Court of New York in the case of the *Hudson River Telephone Company* v. *The Watervliet, Turnpike, and Railroad Company*. The importance of that case was that it was a judgment of the Supreme Court of New York, and, so far from it being a judgment supporting the principle which his learned friends contended for, it was actually a case in which they ordered a new trial because the judge had not directed the jury that the Telephone Company could recover in the event of the currents coming off from the tramway undertaking, and thereby causing the injury to the property. The date of the judgment was Sept. 9, 1891.

Mr. DUNHAM: I think that has been reversed.

Sir R. WEBSTER: It is very unlikely, because a new trial was directed. The Supreme Court of New York can scarcely have been reversed.

Mr. JUSTICE KEKEWICH: It is the Supreme Court of New York. Not the Supreme Court of the United States.

Mr. DUNHAM: I am told that that is a judgment on an interlocutory point, but that the main question in the action was subsequently decided contrary to that.*

Sir R. WEBSTER, after quoting English authorities, said that his learned friend, Mr. Bousfield, spoke as though the single-wire system was only the system of one company. The evidence before the Court was that more than nine-tenths of the telephone business was done on the one-wire system, and the only suggestion was that, in places where there was very acute disturbance from other causes, as in London, it might be desirable to have another system. He had only to say in conclusion that he asked the Court to lay down no harder rule than that the defendant was not to conduct his business so that he interfered with the business of the Telephone Company lawfully carried on, and entitled to the protection of the law.

The SOLICITOR-GENERAL, at his Lordship's request, then referred to further cases bearing on the action occupying the attention of the Court, and was again followed by Sir Richard Webster.

Mr. JUSTICE KEKEWICH: I must consider this case, and I will do so as soon as other duties permit. I only wish to say at the present moment, having you all here, that this case strikes me as a very cogent example of the necessity which has been enforced by many Judges, including myself, and lately by different reports of the necessity for the power of bringing an action before a competent tribunal after issue joined in order that the method of procedure may be determined. I cannot help thinking that if this had been brought before a Judge in Chambers to settle what should be argued, we should have saved several days' evidence, and should have come to a satisfactory conclusion in not only a much quicker way, but, what is the result of quickness, much less costly. I cannot blame anybody; I do not blame anybody; but it is a reform that has been near my heart for a long time, and I cannot help enforcing it.

Macintosh v. Siemens.

This was an action brought under the provisions of the Employers Liability Act, in which the plaintiff sought to recover damages for personal injuries sustained owing to the alleged defective condition of the defendant's plant at their electric light works at Greenwich. The plaintiff's case was that on July 22nd last he was ordered to go to work on a lift which was being constructed for the purpose of testing the utility of electricity as a motive power. In the course of his work he was ordered to go across a plank, and in carrying out that order he slipped and fell to the ground, with the result that both his legs were fractured, and he had aver since been incapacitated from work.

For the defence, it was alleged that the work which the plaintiff had to do was perfectly safe if he had chosen to use proper and ordinary care. It was absolutely denied that the beam from which he fell was in a "wobbling" condition, or that it was by any means unsafe. The defendants' foreman and several other witnesses were called to prove that the beam in question was part of the permanent structure, and was in the same position at the present moment as it was on the day of the accident.

After hearing the case at great length his Honour told the jury the questions which they had to consider were as to whether the defendants' plant was defective, and if it was, whether the carpenter was guilty of negligence in ordering the plaintiff to do work of an unduly dangerous nature.

The Jury, after a short consultation, found that there was no defect in the defendants' plant, and no negligence on the part of their foreman or any other servant.

His Honour entered judgment for the defendants, and made a formal order for costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan.* 14, 1893.

Gilbertiana.—The discussion stirred up on your side of the Atlantic by the note which appeared in the American letter of a few weeks ago has reached this side of the water, and is being taken up by the American journals. Last week the *Iron Age* devoted a page or more of space to this subject, giving a reprint of Prof. Thompson's first letter to *The Electrician*, with Mr. Dredge's reply, and supplemented by another reply to Prof. Thompson's letter written by Messrs. John Wiley and Sons, the publishers, to the editor of the *Iron Age*. A number of electrical journals have also taken up the subject, and given more or less space to the matter. The general opinion seems to be that Prof. Thompson has unnecessarily stirred up a discussion on this subject, and it is quite generally agreed that Mr. Mottelay, or anyone else, has a perfect right to translate and publish Gilbert's work in the English language, irrespective of whatever the Gilbert Club might be intending to do. The journals, however, have not yet commented on Prof. Thompson's latest reply, which appeared in *The Electrician* which came to hand this week, and it may be that this letter will change the opinion of some American journalists in regard to Mr. Mottelay's action prior to his announcement that he was bringing out a translation. It is generally understood in this country that Mottelay's translation will be issued from the press in three or four weeks at the latest, and that the only reason it is not now on the market is because of the desire on the part of the publishers to protect the English copyright on the work. Some interest is manifested in the anticipated reply of Mr. Dredge to Prof. Thompson's latest letter.

Storage Battery Traction.—This form of traction seems to be a favourite system for "experiments" in New York. For a number of years system after system has been tried on different lines of street railway, only to disappear in a month or two and to give place a little later to another system operated by another company in a different part of the city. A trial was made this week on one of the lines of a storage battery system, which had been announced as the coming thing in the storage battery line. Speed tests had previously been made by the General Electric Company's engineers, it is said, which showed that on a 6 per cent. grade the car ascended at the rate of 6·7 miles per hour. The trial trip made this week showed a speed on the same grade of something like two or three miles per hour, although it should he said in fairness that the track was in rather poor condition. Less and less confidence is coming to be placed in the storage battery for electric traction purposes. That the storage battery and the storage battery car will work there seems to be no question, but that it will work economically has yet to be shown, and until this can be shown Yankee investors are likely to prefer the overhead trolley, which has already shown that it can be ecomically operated under nearly all conditions of street railway traffic in other than the very smallest cities.

CORRESPONDENCE.

VOLTAMETER EXPERIMENTS WITH AN INDUCTION COIL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Paper of Dr. Magnus Maclean, of which you print an abstract in *The Electrician* of January 20th, is of interest as an attempt to show the magnitude of the current at break in the secondary circuit of an induction coil, by arranging a vacuum tube and an electrolytic cell in series in the circuit, and weighing the electrodes after the coil had been in action for a certain period of time. In this way Dr. Maclean arrives at figures giving about one-sixth of a milliampere as the average current in the secondary circuit during a period of 4,200 seconds in a particular experiment. But

Hosted by Google

when an induction coil is acting, a very large proportion of the whole time is made up of the intervals between the successive contacts of the vibrator. Dr. Fleming has quoted* some experiments of Blaserna in which the duration of the impulses in a secondary coil were measured, the times arrived at for a particular coil were 0·000485 sec. for the current at make, and 0·000275 sec. for the current at break. If we suppose that the currents at make were all stopped off by the vacuum tube, and if we take the fairly rapid frequency of 400 a minute for the rate of vibration of the contact breaker; then the total duration of the break currents in the secondary per minute amounts to 0·000275 sec. × 400, which gives 0·11 sec. Thus, out of each minute there is wasted time to the extent of 59·89 sec., or, in other words, the break currents pass through the electrolytic cell for 0·183 per cent. of the total time. Consequently, in one of the experiments reported, where the current calculated from the gain of weight in the copper electrode is 0·1669 milliamperes in a period of 4,200 sec., a correction should be made for the actual time of the passage of the current; and if Blaserna's figures are used, the real time during which the copper was deposited comes out as 42 sec. × 0·183, or 7·686 sec., and the average current during this period becomes 91 milliamperes instead of one-sixth of a milliampere. Even if the times given by Blaserna are not quite applicable to the particular coil used by Dr. Maclean; and even if the contact breaker may have acted with double the frequency which has been assumed, it still remains quite evident that large corrections must be made for the time during which the secondary coil is carrying no current.

In the same Paper Dr. Maclean gives figures to determine a ratio between the current in the primary circuit and the current in the secondary; but here, also, corrections are necessary, for the total current in the primary must depend largely upon the time during which the parts of the vibrator are in contact, and the current in the primary would be greatest when they were in contact all the time, in which extreme case the current in the secondary would be at a minimum.—Yours, &c.,

H. L. Jones.

HYDRAULIC MAINS AS A SOURCE OF POWER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your review of Mr. Segundo's book on "Domestic Electric Lighting" you mention his suggestion of the hydraulic power mains as a source of power in a rather disparaging manner; yet, if fitted in a proper manner, I think it affords a very convenient, if not a very economical, power for small houses, as all that has to be done is to turn on the water and the machine starts.

As to cost at 10s. per 1,000 gallons, 1 B.H.P. on the spindle of a Pelton water-wheel would cost 1s. 6d. per hour, taking the head at the nozzle as 1,650ft. = 710lb. per square inch, or 1s. 9½d. at 600lb. only.

The diameter of a Pelton water-wheel to run at 3,000 revolutions per minute under 700lb. pressure would be 12in., and diameter of jet to give 1 H.P. would be about 0·08in., taking coefficient for the jet at 0·68.

With the extension of electric light mains all over London, the need for such a plant as I have here roughly sketched out is probably gone past, but in certain cases it might prove useful.

A gas engine would be cheaper in working, but would cost more to erect and keep in repair, besides being much more bulky, as the hydraulic machine being well balanced might run at a much higher speed.—Yours, &c.,

George T. Pardoe.

3, Selborne-place, Littlehampton.

[Taking our correspondent's figures, and a dynamo of 80 per cent. efficiency, and allowing nothing for friction, the cost appears to come to 2s. 6d. per supply unit. But we understand that the London Hydraulic Power Company make a minimum charge of 25s. per quarter, for which sum they supply 3,000 gallons (*The Engineer*, January 20, 1893, p. 46). This comes to 8s. 4d. per thousand, and reduces the 2s. 6d. to 2s. 1d. It would be very difficult to apply a governor to a supply of water at this pressure, and, therefore to work below full load without increasing this already serious cost. We understand that the Exchange Telegraph Company use a dynamo driven from the Hydraulic Power Company's service by a Pelton wheel.—Ed. *E.*]

* "The Alternate Current Transformer," Vol. I.

TRADE NOTES AND NOTICES.

Our readers are reminded that the 1893 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now in the press, and will be ready in a few days. Firms and others who have not returned the slips asking for information are requested to do so *immediately*. The price of the Directory and Handbook will be as before: *Subscription*, 5s.; after publication, 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

Tenders Invited.—The Corporation of Nottingham invite tenders for the supply and erection of boilers at their electric lighting station in Wollaton-street, Nottingham. Some further particulars are given in our advertisement columns, and specifications and all other information can be obtained on application to the electrical engineer, Guildhall, Nottingham. Tenders have to be sent in to Mr. S. G. Johnson, town clerk, not later than Thursday, 16th February.

Tenders Accepted.—The Town Council of Bournemouth have accepted the tender of Messrs. Goddard, Massey, and Warner, for the electric lighting of the pier. Six tenders were received.

——— The tender of Mr. W. Winn, 106, Union-street, Borough, S.E., has been accepted for the gas fittings and electric installation at the Old Crown and Cushion public-house, Westminster Bridge-road, S.E., at £295.

——— The tender of Messrs. James Maxwell and Sons, of Dundee, has been accepted for the wiring, &c., of the Town House for the electric light. The amount of the tender is £140, the highest tender being £260.

Improvers Wanted.—The Hull Corporation are prepared to take two improvers into their electric light works. Particulars appear in our advertisement columns, and applications must be delivered to Mr. F. Harman Lewis, borough electrical engineer, by Feb. 9th.

Plant for Sale.—Messrs. Wheatley Kirk, Price and Goulty advertise for sale a number of engines and boilers by the best makers.

Australasian Electric Light, Power, and Storage Company (Limited).—Mr. J. H. Duncan and Mr. B. H. Van Tromp, of 39, Coleman-street, E.C., have been appointed liquidators in this winding up. All claims must be sent in by Saturday, March 4th.

In the Matter of A. B. Gill.—The creditors of Arthur Bernard Gill, who have not already sent in their claims, are required to do so before February 24th to Mr. A. T. Clarke, of 6, Lombard-court, E.C., the trustee. Further particulars will be found in our advertisement columns.

City of London Lighting.—The City of London Company give notice that, unless prevented by unforseen circumstances, electric energy will be laid on within the next few months in the five areas in the City of London known as (1) Nicholas Cole Abbey sub-area, (2) Finsbury-circus sub-area, (3) Salisbury-square sub-area, (4) Billiter-square sub-area, and (5) Farringdon-street sub-area. The Company anticipate that very shortly a further list of these sub-areas will be issued. Further particulars will be found in our advertisement columns.

The Johnston System of Conduits.—The City of London Electric Lighting Company have decided to put down the Johnston system of conduits in John Carpenter-street, close to the Blackfriars District Station. This is the first opportunity the International Electric Subway Company, Limited (who own the system), have had of showing the subway in actual work in London, although many hundreds of miles have been laid in America.

Shippey Bros. (Limited).—We are informed by Mr. A. Shippey that this Company have been appointed European agents for the fuse wires manufactured by the Sperry Electric Mining Machine Company of Chicago.

Messrs. Rashleigh Phipps and Co.—This firm have secured the contract from Messrs. Duveen Bros. for completely installing their extensive premises in Old Bond-street with the electric light.

Oxford University.—Mr. Morgan Williams (Messrs. Morgan Williams and King) has been instructed by the Bodleian Curators to report on the proposed electric lighting of the buildings under their control.

Hosted by Google

SOCIETE GENERALE DES TELEPHONES.—This Company, whose offices are at 41, Rue Caumartin, Paris, and for whom Mr. G. A. Nussbaum, 29, Ludgate-hill, E.C., is general agent in England, have just issued a new catalogue of nearly 200 pages, dealing fully with the various specialities manufactured by the Company. More than 250 illustrations are included in the catalogue, showing the large variety of instruments the patents of which are owned by the Société, which comprise all kinds of telegraphic and telephonic apparatus, registering instruments, batteries, &c.

MESSRS. O. BEREND AND CO.—This firm issue a handy pocket catalogue, giving illustrations of a large number of specialties which the firm supply.

NON-SPLITTING FILE HANDLES.—Messrs. F. Kühn and Co. have lately introduced a soft non-splitting file handle made of specially prepared pulp, which is warranted not to split. The ferrules do not fall off, and a large file can be driven into a small handle without cracking it.

CALENDAR FOR 1893.—The New York Equipment Company are to be congratulated upon the issue of a neat pocket memorandum tablet and calendar, which is made of imitation ivory and is very neatly designed.

ABERYSTWYTH.—The question of the electric light for this town is again creating attention, and the Public Lights Committee recommend the Council to enter into a provisional agreement for a grant in perpetuity of a water-course for the purposes of the electric lighting scheme.

BRYNMENIN.—Messrs. Jones Brothers, brewers, have, in addition to lighting their own extensive premises at Brynmenin, entered into an arrangement with the Ogmore and Garw Local Board, by which they are to light the village of Brynmenin by electricity.

CARDIFF.—At the last meeting of the Corporation Mr. Alderman Jacobs said that the Committee desired it to be made known that the Corporation would be in a position to supply the electric light in the autumn of this year. A deputation waited upon the Committee to complain of the insufficient gas lighting of some of the main streets of the borough.

COWPEN.—Friction still exists between the Electric Lighting Company and the Local Board, the subject which now causes dissension being as to whether certain fines imposed upon the Company by the Board are instituted by circumstances over which the Company has no control.

DUNDEE.—At the last meeting of the Works Committee of the Gas Commission it was statad that the new central station was practically complete, and that the light would be introduced in about a fortnight. The electrical engineer was instructed to appoint an efficient staff for the station. Subsequently it was decided that the question of lighting the Old Steeple and the Police Office by electricity should be submitted to a sub-committee to discuss and to obtain tenders.

EDINBURGH.—The report of the deputation recently appointed to visit the principal southern central stations has been issued. The deputation state that they early ascertained that a large number of local authorities throughout the Kingdom had preceded them in their visits to the various stations, showing the interest taken in the subject throughout the country. Every opportunity was offered the deputation at the stations visited to make themselves thoroughly conversant with the subject. A considerable portion of the report is taken up with details of plant and working at the various stations visited, which include Newcastle (2), St. Pancras, House-to-House, West Brompton, Westminster Electric Supply Company, City of London Electric Lighting Company, St. James's and Pall Mall Electric Light Company, Cambridge, Bradford, and Oxford. The report was subsequently submitted to the Lord Provost Committee, and after some discussion it was referred back to the Electric Lighting Sub-Committee to frame a report to submit with their suggestions to the Council. The discussion which ensued arose chiefly upon the point whether it would be preferable for the Corporation to deal with the subject of electric lighting, or whether it would be better to hand the matter over to a local company to work.

FOOTBALL.—The electrical staffs of Messrs. Siemens Brothers and Co. (Limited), and Messrs. Johnson and Phillips will play a match under Rugby rules at Charlton Park (Weeke's-lane entrance) to-morrow (Saturday), commencing at 2:45 p.m. sharp.

HOVE.—Mr. Frank King (Messrs. Morgan Williams and King) has been appointed by the Town Commissioners of Hove to report to them regarding the tenders for the electric lighting of the Town Hall.

HAMMERSMITH.—All the necessary documents in reference to the draft of the Provisional Electric Lighting Order have been lodged with the Board of Trade. We understand that no notice of objection has been received by the vestry.

HUDDERSFIELD.—The Finance Committee have appropriated £2,000 from the Mayor's fund in connection with the installation of the electric light in the Town Hall.

IPSWICH.—The subject of the electric lighting of Ipswich again came before the Local Board at their last meeting, and hopes were expressed by several members that steps would be taken to reintroduce the light.

JOHANNESBURG (S.A.R.).—The Johannesburg Electric Light Company are making considerable additions to their electrical plant in order to keep pace with the growing demand for the light. It is expected that in the beginning of February they will be able to supply the electric light to shop-keepers only requiring occasional displays. This class of customers has not previously been catered for by the Company.

MELBOURNE.—The Electric Club of Victoria held its annual dinner on the 14th ult. The club numbers 45 members, and is likely to be a similar success to the one started in New South Wales eighteen months ago. It is proposed to devote the summer months to excursions to installations of interest, and the winter months to the discussion of papers to be read before the club. The members include all the electrical men in the colony, and a number of other persons interested in electrical matters.

NATIONAL CYCLE SHOW.—On a visit to the Crystal Palace we searched diligently for incandescence "head lamps"—but in vain, and curiously enough the small dynamo to be driven by the "waste power" of a rider, though often talked about, was nowhere to be seen.

NEW TELEPHONE COMPANY (LIMITED).—The second annual *conversazione* of this Company's *employés* in the Manchester district was held at the offices in Portland-street, Manchester, on Friday evening last.

PRIVATE BILLS IN PARLIAMENT.—Amongst the cases in which the required proofs have been given before the examiners (Mr. Campion and Mr. Thoms), in compliance with the Standing Orders regarding Bills deposited for the ensuing Session, was included the Edinburgh Corporation Tramways Bill allowing the Corporation the use of cable or electrical power on the lines belonging to or to be acquired by the Corporation, and also a measure to authorise the Glasgow Corporation to construct additional tramways.

READING.—At the last meeting of the Town Council the draft Provisional Order was presented, and a resolution to the effect that the Council consent to the granting of a Provisional Order to the Reading Electric Light Supply Company (Limited) was carried.

SANDGATE.—A special meeting of the Local Board is to be held for the purpose of considering the expediency of acceeding to an application made by Mr. S. Sellon, of Parliament-street, Westminster, for permission to adopt electric traction to the Sandgate tramways. The scheme is for an overhead side-suspension system, with poles 20ft. apart. Mr. Sellon, if his proposal is accepted, will include arrangements for lighting by electricity the whole extent of the sea wall.

SOUTHAMPTON.—A proposal to light the Audit House and Public Offices by the electric light, at a cost not to exceed £180, came up for discussion at the last meeting of the Town Council, but in view of the opinion expressed that new municipal offices would soon be necessary, the consideration of the matter was deferred.

THE TELEPHONE.—Speaking at a meeting, last Monday, of the London Chamber of Commerce, Sir Albert Rollit, M.P., observed that, with respect to the question of the telephone, he had said in Parliament—and he thought so still—that the Government could do more than private enterprise, and he thought that there were illustrations of this in some foreign countries. He thought, however, that there was some misapprehension in supposing that London and the country generally would not derive considerable benefit from the new system. The Government had taken up the trunk wires, and town and town would very soon be able to communicate with each other. Within a few yards from where they were then assembled (Eastcheap, London, E.C.) they could communicate with Hull, and the public would have similar opportunities elsewhere soon. It was easy to speak with Marseilles; and he believed that at no distant date they would be able to speak across the Atlantic, and have visual representation of the person with whom they might be conversing. He believed this to be not a mere guess, but a fair inference from what science had already accomplished. What had been done on a very large scale in America was now being done in this country. He had seen what an admirable system of development of the telephone had taken place in Denmark, and he believed at no distant time that London would have the benefit of the most efficient system—a complete metallic circuit, and in all respects the most efficient instruments that could be provided; that, through negotiations now pending with the Commissioners of Sewers and the Electric Lighting Companies, underground would largely replace overhead wires, and, in fact, that London would have what it ought to have, the best and most modern system of telephonic communication that could be devised.

Hosted by Google

TORPOINT (DEVON).—For some months past there has been considerable friction between the Gas Company at this place and a large section of the ratepayers, the latter complaining of the cost of the gas lighting, and that the proposed imposition of a sixpenny rate is an attempt to make up the Company's dividend at the ratepayers' expense.

TORQUAY.—At the last meeting of the Town Council the Electric Lighting Committee suggested that, having regard to the financial position of the Borough, offers be invited from those willing to take over the powers possessed by the Council under the Provisional Order for 1891. An amendment was carried that the matter be referred back to the Committee and that a specialist be called in to advise.

YORK.—Seventeen tenders have been received for the electric lighting of this city, and it has been resolved to appoint Prof. Kennedy to advise the Electric Lighting Sub-Committee on the subject.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The forty-first half-yearly ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. George Draper) read the notice calling the meeting, and the minutes of the past meeting, which were approved by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN, in moving its adoption, stated that the gross revenue for the half-year ended September 30th had been £352,391, or a decrease of £2,548, compared with that of the corresponding period of 1891. In analysing the message receipts they found decreases in the traffic with certain places, which were almost recouped by the increases in other places. There was no considerable fluctuation in any way, and the amount received from their investments in other companies was practically the same as in the corresponding period of the previous year. The total working expenses for the half-year had been £98,797, being an increase of £1,666; but expenses attending repairs and renewals of cables, &c., had amounted to £37,636, being a decrease of £9,411, compared with those of the corresponding period of 1891. In addition to keeping their own cables in a state of efficiency they had been doing work for the South African, West African, and the Brazilian Submarine Telegraph Companies; and the amount received from these companies, together with their having had to expend less cable on their own repairs, had had the effect of reducing the expenses under this head, which had enabled them, notwithstanding the reduction of £2,548 in their receipts, to carry forward to next half-year £62,847, or £5,338 more than at the corresponding period of the previous year. He might mention that they had received during the half-year from other companies £15,610 for the hire of this Company's ships. As they would have noticed from paragraph 6 of the report, the Directors offered to the holders of the Five per Cent. Debentures, redeemable at par in 1899, the option of exchanging their security for the Four per Cent. Mortgage Debenture Stock of the Company. This offer was responded to by holders of nearly one-half of the debentures. The debentures being to bearer they had to reach the holders through the medium of bankers, brokers, &c., who had presented the last coupons for payment, and in cases where the Directors' circulars had not reached the holders, they would be glad to consider the application of any one who was still desirous of affectng the exchange. All particulars as to terms could be obtained at the Company' office. The holder of the mortgage debenture stock was placed in a better position than he stood in by the old bond, which was quoted that day at something like 7 premium, whereas the new mortgage debenture stock stood at something like 10 premium. For those who wanted a permanent investment the Four per Cent. Perpetual Security which the Debenture Stock afforded was beyond all question a very sound and safe one. A storm had interrupted their land lines at Cairo, and the sea had not been altogether free from disturbance. The result was that during the past month they had had many repairs to make; but he was glad to say that every year taught them more how to deal with these repairs, and more and more established their cable system as a property. Last month they had about ten broken cables, and took out 30 faults. All this proved that they had their property very much in hand, and that their ships were very generally employed. The system they had adopted of duplicating the cables also made the continuity of their system so reliable that the public rarely knew when any interruption occurred. He desired very briefly to refer to Egypt, which was one of the Company's great stations, and they had a very important traffic with that country. He frequently went to Egypt and saw the working of the English system in force, and all he could say was that he believed there was not a better governed country in the world than Egyp was at the present time under English administration. The men of experience who had charge of affairs were working with an unselfish motive, their only selfish desire being that they might command the respect and grati

Hosted by Google

tude of the people of Egypt by their just and wise government. They had heard a few days ago of the little trouble that had arisen, but it was insignificant for the men who were there representing this country's interests and those of Egypt to deal with; and he had no fear that any trouble would arise out of it. They had no politics in their company, and the better Egypt was governed the better would be the traffic on their telegraph system in connection with that country. They were also on very friendly terms with Turkey. Rather a remarkable speech was made recently by a gentleman who had a European reputation, he referred to Mr. Rhodes, and it was men like Mr. Rhodes who were required in developing a new country where great ability and great energy were required. Mr. Rhodes was endeavouring to open up Africa, and he proposed eventually to carry through Africa on to Cairo a telegraph system which he thought some day would enable him to carry telegrams from the Cape to Europe for something like 2s. against this Company's charge of 9s.

Sir JAMES ANDERSON (the Managing Director): 4s.

The CHAIRMAN, continuing, said that he did not know whether Mr. Rhodes said 2s. or 4s. The projected line, however, had to pass through countries other than those which were under the control either of England or Mr. Rhodes. The Mahdi controlled a portion of the country through which it was proposed to carry the line. He thought that by the time Mr. Rhodes got his telegraph to Wady Halfa this Company would have paid off their debentures, and would probably then have a capital of not more than that which Mr. Rhodes proposed for carrying his telegraph system through Africa. Meantime, every territory that was passed through depended upon Mr. Rhodes finding gold, and if he did find gold his line must of necessity become a feeder to the Eastern Company for a great many years to come. He mentioned these facts in order to relieve the minds of any of their shareholders on the point, and to show them that, instead of the projected line being a competitor, for twenty years to come it was much more likely—if it went on—to be a feeder to this company. When Mr. Rhodes' line reached Cairo, and he hoped the country would be so developed as to enable him to get there, their Company would be very ready and willing to meet him upon his own ground; and he thought the chances were, looking to the greater security which he might say existed in a submarine system as against a land line, that the Company would not only be able to do the work more accurately and more quickly, but also probably cheaper than the projected land line. At the same time he wished Mr. Rhodes every success in opening up this dark country. It was a long way from Cape Town to Wady Halfa, and when he got to Wady Halfa he would be in the hands of the Egyptian Telegraph Executive. They had just settled, through the Eastern Extension Company, with which their Company was very closely connected, the question of a slight advance in the rates to Australia. The reduction which took place in the rates was from about 10s. to 4s., the Governments guaranteeing the return which the Company was receiving at the time the reduction was made. It was found, however, by the Governments that the loss of revenue by the reduction in the rate was not recouped so rapidly as had been expected, and when they asked for the rates to be advanced by 9d. the Board did not think they ought to stand in the way of meeting the wishes of their co-partners. The change had been most successfully carried out, and as far as they could see at the present time they would, he believed, be able to get back a little more of the former revenue and reduce the loss which had been sustained owing to the very large reduction originally made. Since their last meeting they had made a contract with Her Majesty's Government, in which India was interested, to lay a cable from Zanzibar to Seychelles and to Mauritius. For this the Company would get a guarantee for twenty years of £28,000 a year. Altogether, their Company was probably in as strong a position as it was ever in, and their property was increasing in value and likely to become still more valuable.

Sir JAMES ANDERSON afterwards explained on the map the country through which the projected line of Mr. Rhodes was intended to travel, pointing out the difficulties which would be encountered in the course of the work.

The CHAIRMAN afterwards stated that they had just received an announcement that their land lines were in order to Cairo. As there had been a little difference between Sir James Anderson and himself respecting Mr. Rhodes's proposed tariff, he would read what that gentleman had said on the subject:—"This line to Egypt, provided the Mahdi is "squared," will cost £300,000 to £400,000, and we have lying to the east and west of the coast (that is our system) cables which cost over £3,000,000. We are now charged 9s. 6d. a word for our communications, but when we can get to Egypt by the telegraph I am referring to, we shall be able to do it for 1s. 7d. from Egypt to England, or in all about 2s. 6d., against 9s. 6d. a word." He afterwards proposed a resolution for the adoption of the report.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion, which was unanimously adopted, and resolutions were afterwards passed, re-electing the retiring Directors and auditors.

On the motion of Mr. BURGESS, a vote of thanks to the Chairman and Directors was passed, and the proceedings then terminated.

(*We shall publish a full report of this meeting in our next issue.*)

St. James' and Pall Mall Electric Light Company (Limited).

The ordinary meeting for 1893 of the shareholders of this Company was held at the Company's central station, Carnaby-street, Golden-square, W., on Tuesday last, Mr. Eustace J. A. Balfour presiding.

The GENERAL MANAGER and SECRETARY (Mr. F. J. Walker) read the notice calling the meeting, the report of the Directors and statement of accounts being taken as read,

The CHAIRMAN: The next business is the moving of this resolution:—

"*That the report and accounts for the year ended 31st December submitted by the Directors be received and adopted, and that the dividends recommended be declared and paid on the 1st of February.*"

Mr. LATIMER CLARK: I second that.

The CHAIRMAN: Gentlemen, in moving the adoption of the report and accounts, I think that it will be of interest to the shareholders if I briefly enter into a few matters in connection with the year's working, and with the present condition of the affairs of the Company. We may look back upon the past year with satisfaction. There is, it is true, nothing showy or brilliant in our report, and the dividend which we recommend, although not so large as some may have ventured to anticipate, yet shows that the business possesses a most satisfactory earning power. For it must be borne in mind that in the future we have every reason to suppose that our earnings will increase, without any considerable additional capital expenditure. One of the most curious features in the year is the economy which consumers now exercise as compared with former years. This may best be shown by noting the relative increase in the gross income from supply of light and of the number of lamps wired. The latter is 24·4 per cent., while the former is only 10·4 per cent. Had our gross income increased in proportion to the number of lamps wired our net earnings would have enabled us to pay a much larger dividend. Looking, however, at this matter broadly, I think that it is probably a good feature in the business. Because I think that many would-be customers have hitherto held aloof, owing to a general belief that electric lighting was excessively costly. A very satisfactory feature in the year's working is the saving which has been effected in the cost of production. Thus the consumption of coal has been diminished by ¼lb. per unit sold, while that of water has been reduced from 13·6 to 11·75lb. per lb. of coal. Dealing with these figures the editor of *Lightning* says:—"From these figures it will be seen that Mr. Crompton's 'sheer costs' estimate is more than realised. *Total costs* show altogether a reduction of ¼d. per unit, which cannot be regarded as otherwise than very satisfactory, and reflecting the highest credit on Mr. Dobson, the Company's able engineer," a remark with which the Directors cordially agree. It is our intention to maintain, and if possible to increase this economy. While on this subject I think that you should realise that our economical management does not apply to cost of production alone, but also to capital expenditure. In this we compare very favourably with other metropolitan companies. I evidently cannot particularise, but our capital expenditure per unit of capacity is satisfactorily low. Indeed, there is one company which has spent about double what we have done, while the most favourable is considerably ahead of us. These results have only been obtained by the most rigid and continuous supervision. You will notice that there has been a considerable reduction in the amounts set aside for depreciation of plant and machinery. After careful consideration the Directors came to the conclusion that the very large expenditure on repairs, maintenance and renewals justified this reduction. But the putting of depreciation at a just valuation is a matter which will have to be considered in each year on its own merits, as the conditions are constantly varying. For instance, a few days ago serious damage was done to one of our engines in Mason's-yard by the breaking of the crank shaft. We cannot be free from such accidents, which indeed must be regarded as inseparable from the wear and tear of our delicate machinery. We regret extremely the result of the action brought against the Company by Dr. Hopkinson in respect to the three-wire patent, and are carefully considering what further action to take in the matter. An idea seems to have got abroad that our supply can thereby be stopped. This is not the case, as arrangements have been made by which, if necessary, the supply can be continued without further infringement of the patent. We cannot at this time go into further detail. On June 7th last four members, representing some of the founders' shareholders, Mr. Charles Fry, Mr. W. Sturdy, Mr. Geo. Kitchin, and Col. Francis, issued a circular, calling a meeting of founders' shareholders to consider certain matters in connection with the management of the Company, which they regarded as detrimental to their interests. The Directors, while of course they are bound to consider the interests of the whole body of shareholders only, were anxious to discuss these matters in a friendly way with the representatives of the founders' shareholders, and a meeting was consequently arranged between delegates from the two. The first point complained of is "that the Directors did not bring forward for division as profit the £15,000 received by them as premium on 10,000 shares issued on December, 1891, but intimated that they had carried it over to a capital reserve fund." Now, in reference to this complaint, I have to note that the Directors in the prospectus as to the issue of those shares stated that the amount derived from this premium would be put to a capital reserve account. It was under this condition, therefore, that the shares were subscribed for. Thus, the Directors could not alter the arrangement if they would. Further, those owners of founders' shares who applied for shares, acquiesced in this arrangement, and had notice. But if these shares had been issued at par instead of at a premium, the founders' would not have benefited. We should, in this case, have issued Five per Cent. Preference Shares instead of Seven per Cent. But as a sum equal to 7 per cent. on the *whole* capital of the Company has to be paid before the founders' are entitled to receive any dividends, they would have been as far as this is concerned in exactly the same position as now, and they would not have the contingent benefit of a quarter of this £15,000 in case of a winding-up of the Company. All classes of the shareholders benefit alike by the strengthening of the Company owing to the existence of this capital reserve fund. The next point raised by the representatives was that an excessive amount had been written off for depreciation. I have already dealt with this subject, and can only repeat that in each year the Directors will do their best to arrive at a just valuation of the amount that should be written off. They are quite at a loss to discover

Hosted by Google

on what grounds the statement in the circular is based. The next objection raised is to the formation of the special redemption fund. The Directors have carefully considered the representations made to them on this subject, and they feel very strongly that the course they have adopted is not only right in itself but will meet with the approval of the shareholders generally. It would no doubt be very pleasant to divide the £2,000, which this fund now amounts to, as profits, but it would not be sound finance. Under the Electric Lighting Acts our property may be, and probably is, a vanishing security. In many ways it resembles an investment in leasehold property. We therefore feel bound o create this fund. In all these matters the Directors have considered he well-being of the Company as a whole, and not the special interests of any one class of shareholders. But even thus it is worth noting that in the direction of big profits the interests of the founders' and ordinary share holders are identical, since for every pound given to a founders' shareholder a corresponding pound is divided amongst the ordinary shareholders. I fear I have already kept you too long, and I fear that our accommodation here is not luxurious. In conclusion, I shall be glad to do my best to satisfy any gentleman present who may seek information.

Mr. FRY wished the Chairman to complete the whole story by placing before the shareholders the letter of the 21st December from the representatives of the committee of the founders' shareholders and the reply thereto. He wished further to know whether any steps had been taken by the Board to see that a full report of the meeting should be sent to every shareholder. This was a question raised at the last meeting. It was a practice followed by other Companies, and he thought that every shareholder should have a verbatim report of the proceedings. Turning to the report, he thought that the shareholders must feel a certain amount of disappointment that they had not been able to get on faster with the central station, where they were now assembled. Of course, circumstances might have arisen—such as the difficulties connected with ancient lights, and other matters—to impede their progress; but it would have been much more satisfactory if the station had been opened for the last few months, because it would have been earning a dividend, instead of which they had been paying interest on capital which had been entirely unproductive. He would now pass to No. 6 paragraph, which dealt with the question of the redemption fund. They must be aware that there were such things as the rights of the founders' shareholders. Those rights were clearly pointed out in the first form of the Memorandum of Asssociation, and they were repeated in the Articles of Association subsequently passed. There was another point which he would like to mention—that the founders' shareholders maintained that they had a right to the division of this redemption fund among the shareholders. He was strongly of opinion that they had. This was not their own opinion only, for they had taken the advice of counsel on the subject, and they meant to contest their rights. Another point which he desired to state, was, that the ordinary shareholders had rights as well. If they took into consideration the various provisions in connection with the Electric Lighting Acts, he thought that they were not likely to be ultimately bought up as appeared to be the prevailing opinion. With regard to paragraph 7, as to which he would have to ask some questions presently, and which dealt with the action brought against the Company by Dr. John Hopkinson, he did not think that the Directors had shown that their judgment had been very sound. Possibly they would find that on this subject, and especially on the question of the redemption fund, the vendor and shareholders were right, and that the directors were wrong. He would ask whether it was not possible for the latter to alter their opinion at the last moment? It was said in paragraph 6 that "this question was before the meeting of the members of the Company last year, when the creation of the fund was approved *nem. con.*" He would not dispute that, but if they would look at the reports of that meeting, it would be seen that there was great opposition to it. He saw that Mr. Muirhead raised the question, and particularly pointed out the items of depreciation, which he considered ridiculous. The fact was that the recommendation of the Directors was not carried *nem. con.*; because there was opposition to it in the room. He would like to ask whether the opinion of eminent counsel had been taken on the point. As to the alleged infringement of the three-wire patent of Dr. John Hopkinson, he wished to ask by whose advice it was that they adopted that system, because he presumed that it was possible to find out what were patents and what were not patents. Their adopting it had ended, it appeared to him, very disastrously to the Company. He would reserve his right to move an amendment later.

Col. FRANCIS detailed the circumstances under which last year the depreciation account was considered to be excessive by some of the shareholders. The most material point on which the committee of the vendors, shareholders, and the Board were at variance was as to the scale which should be fixed for depreciation. He quite agreed that there should be a scale, but not a fluctuating one. Depreciation at a certain rate was established in respect to the meters of the Company; but in the case of those meters which had been in existence one or two months depreciation for the whole year was charged. He had appealed to the best authority he could find as to what should be a proper amount for the depreciation of meters, which the Directors had placed at 12 per cent., while the authority referred to had answered him 5 per cent. But the main fact that depreciation for the entire year was charged on instruments which had been in use, say, only three months, was the chief ground of complaint. Then, again, in the report of last year, it was stated that they purchased machinery two years old at the Naval Exhibition, and they said that they had made an excellent bargain in buying that machinery, which had been tried, and yet depreciation was charged on it for the whole year. In fact, depreciation for the whole year was charged on many things at work for only three months.

Mr. SAMS wished to point out that in the memorandum of association it was declared that after the various dividends had been paid, any balance of profits should be divided among the shareholders. He had bought one vendor's share, which he thought would bring him in 5 or 6 per cent.; but he found that he got nothing like that for it. He had bought solely on the statement of the memorandum of association, and what the Directors had done seemed to him to be quite a mistake.

A SHAREHOLDER suggested whether it would not be to the advantage of the Company to buy out the vendors' shareholders.

The CHAIRMAN, in reply to Mr. Fry's first request, read the following correspondence:—

[COPY.]

"5 and 6, Great Winchester-street, London, E.C.
"December 21st, 1892.

"ST. JAMES' ELECTRIC LIGHT COMPANY.

"DEAR SIR: We have been in communication with our clients, consequent on the interview we had with the Directors and yourself on Monday last, and we are now instructed to ask whether, assuming our clients can see their way to narrowing the questions between them and the Company to the one item 'Special redemption fund,' your clients would agree with ours to have that point determined by arbitration, rather than by the far more expensive and protracted means of proceedings at law. Whilst asking you to treat this letter as written without prejudice, we hope it may be taken as an assurance on the part of our clients that they are desirous of terminating as speedily as possible the questions depending between them and the Company.—Yours truly,

"(Signed) LYNE AND HOLMAN.

"S. Morse, Esq., 4, Fenchurch-avenue, E.C."

[COPY.[

"4, Fenchurch-avenue, London, E.C.,
"January 16, 1893.

"FOUNDERS' SHARES.

"St. James' and Pall Mall Electric Light Company (Limited).

"DEAR SIR: Your letter of the 21st came before the Board of the St. James' and Pall Mall Electric Light Company (Limited) at their meeting on Friday.

"The Directors have fully considered the whole position, and are most anxious to deal with and terminate as speedily as possible any question raised by any section of the shareholders of the Company.

"But, as I have already pointed out to you, their position is that they submitted the proposed special redemption fund—to the creation of which your clients are objecting—to their shareholders in general meeting, when the course proposed by them was approved by the shareholders *nem. con.*

"The Board were, and are, of opinion that the creation of such fund was, and is, a prudent and legal course for them to adopt.

"Under these circumstances the Directors do not see how they can, as a Board, agree to submit a question affecting the accounts so approved by the shareholders in general meeting to the arbitration of an outside person.

"Yours, faithfully,

"Messrs. Lyne and Holman." "SYDNEY MORSE.

The CHAIRMAN, continuing, said that the Directors were always anxious to meet the shareholders in every way, and if the meeting finally decided by resolution properly carried that the matter in question should go to arbitration the Board would be bound by such decision. As to the question of sending a report of the proceedings to each shareholder, the Directors did not see that there was any special reason why that should be done; but if there was a strong feeling in favour of the proposal the Directors would fall in with it. He was very glad to think that Mr. Fry considered this to be one of the best companies in London, in spite of the two drawbacks referred to.

Mr. FRY said that there could be no two opinions about the fact that they had the finest staff that an electric light company could possibly have.

The CHAIRMAN said as to the non-completion of the central station that the matter was fully referred to in the report. He thought that if Mr. Fry were only aware of the minute details which the Directors had had to consider, and the care which they had had to exercise to avoid possible litigation, that that gentleman would be rather astonished that the works were so far forward as they were. As to the question of the purchase of the site there for 42 years, it was a very complicated one, and had been constantly discussed by them and their legal advisers. They took the view that it was more than likely that if the local authorities bought up the Company's property at the end of the Provisional Order, which they had a perfect right to do, nothing would be paid to them for goodwill, and all they would get, as Mr. Fry had said, would be the price of old iron. Of course there was a doubt whether the local authority would buy them up or not. He mentioned these things to show that there were really two sides to all these questions, and he hoped it would be considered that the Directors had given them the most careful consideration. It was not a sign of weakness, but rather one of strength to give their attention to such matters. Mr. Fry asked them to remember their decision as to the redemption fund. They were always ready to take into consideration any question brought before them by the shareholders, and he could only say that if it were their wish that the Board should do as Mr. Fry suggested, then they would do so. They were asked further by Mr. Fry under whose advice they adopted the three-wire system. Their view at the time was that it was not a patent, and it was the view of almost every scientific man. Col. Francis was Chairman at the time of it, it was thoroughly gone into before adopting it. A great many scientific men still held that the decision of the judge was wrong.

Colonel FRANCIS said that the scientific adviser to the Company, Mr. Latimer Clark, had assured him over and over again that his firm depended on the three-wire system, and how was it possible to suppose, with their adviser and their designer at their side, that the patent could be contested?

The CHAIRMAN said that, as Chairman of the Company, he was perfectly prepared to accept his share of any responsibility with respect to

Hosted by Google

the action in connection with the three-wire patent, but he did protest most strongly against a former Chairman of the Company coming forward and shirking a responsibility which he with others took on his own shoulders.

Colonel FRANCIS said that he was shirking nothing, and that Mr. Clark and his partners in the firm had said to him over and over again that they possessed the rights; and more than that, by referring to *The Electrician*, it will be seen that those gentlemen were advertising that they were the designers of the system.

Mr. CLARK said that Colonel Francis waa wrong in referring to his firm, which had been a limited company for many years, of which he was chairman. At the time the St. James' Company was formed he became a director of it, but not as a scientific expert, although he had always tried to give the best advice he could. What Colonel Francis thought was the three-wire patent had reference to the ordinary culvert system, and all the arrangements and details of actually carrying out the three-wire system. The patent being fought out was an electrical patent, and had no reference to the shape or form of the culverts, and, therefore, any rights this Company had were the rights to form the culvert, not the patent.

Colonel FRANCIS still maintained that Mr. Clark had led him to understand that he had rights to the patent.

Mr. CLARK: It was perfectly impossible.

The CHAIRMAN, in reply to Mr. Cottrel, said that as to what were the specific arrangements contemplated for carrying out the lighting without infringing any other patents, he did not think that it would be advisable or desirable in the present condition of their machinery that such technicalities and particulars should be discussed. Mr. Kirby just reminded him that although this Company were the actual defendants in the action alluded to, all the electric light companies who used the low-tension system were fighting with them, and would bear their proportion of the cost.

The resolution was then put to the meeting and declared carried by 31 to 7 votes.

Mr. LATIMER CLARK moved and a shareholder seconded the re-election of Sir John H. Morris to his seat on the Board.

Mr. FRY asked whether Sir John was the nominee of other trust companies with which the St. James' Company was connected.

The CHAIRMAN: No.

The motion was then agreed to *nem. con.*

Mr. Gerald W. Balfour, M.P., was on the motion of Mr. CLARK, seconded by a SHAREHOLDER, also unanimously re-elected to his seat.

After some further discussion, and at the invitation of the Chairman Colonel FRANCIS moved the following resolution:—

"*That the question between the vendors and the directors with regard to the redemption fund should be submitted to arbitrators.*"

Mr. FOSTER seconded the motion.

Dr. WEBB moved by way of amendment:—

"*That this subject be left to those who are the trusted guardians of our interests.*"

From what he had heard that day he had greater confidence than ever in the policy of the Board and in the soundness of the Company.

Mr. BOURNE seconded the amendment.

The CHAIRMAN, having put it to the meeting, declared the amendment carried.

Dr. WEBB proposed, and a SHAREHOLDER seconded, the reappointment of the auditors, Messrs. Deloitte, Dever, Griffiths and Co., which was agreed to; and a vote of thanks having been accorded to the Chairman, the proceedings terminated.

Newcastle-upon-Tyne Electric Supply Company (Limited).

A meeting of the shareholders in this company was held last week, at which the Directors' report and balance sheet were adopted, and a dividend of 4 per cent. was declared. The Directors' report (which is accompanied by an auditors' certificate, setting out that the buildings, plant, meters, &c., stand on the balance-sheet at the cost to date, is attached) is as follows:—

The amount of share capital subscribed amounts to £29,920, on which £25,699 has been paid. Besides this, £15,000 has been raised on debentures. The profit and loss account shows a gross profit of £2,300. 5s. 1d., which is reduced to £1,311. 19s. by payment of £988. 6s. 1d. for interest on debentures and on calls in advance. This, added to the amount brought forward, viz., £364. 13s. 3d., makes a total of £1,676. 12s. 3d. to be disposed of. Out of this sum the Directors propose the payment of a dividend at the rate of 4 per cent. per annum, less income-tax, payable on February 1st, which, on the capital as paid during 1892, will absorb £895. 13s. 5d., leaving a balance to be carried forward of £780. 18s. 10d. Out of this amount the Directors recommend that a sum of £600 be carried to a reserve fund, to meet any depreciation that may arise on the Company's assets.

City and South London Railway Company.

The following report of the Directors of this Company for the half-year ended December 31st last, will be submitted to the seventeenth ordinary general meeting, to be held at Winchester House, E.C., on Wednesday next, at three o'clock:—

The receipts from all sources for the past half-year have amounted to £22,652. 13s. 11d., and the cost of working has been £15,389. 17s. 2d, leaving a profit of £7,262. 16s. 9d. Inclusive of the balance brought forward from June 30th last, the net revenue account shows an aggregate total of £8,304. 12s. 2d. After making provision for the debenture and debenture stock interest, amounting to £4,258. 19s. 2d., a balance remains available for dividend of £4,045. 13s. 0d. Out of this sum your Directors recommend the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of ⅝ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £822 to be carried forward to the next account.

The number of passengers conveyed during the six months ended December 31st, 1892, exclusive of season ticket holders, was 3,217,602, showing an increase over the corresponding period of the previous year of 468,547.

Your Directors have satisfaction in reporting that the service of trains has been carried on during the whole of the half-year with great regularity, and with an almost entire absence of any interruptions whatever, whilst the receipts from traffic have increased considerably.

The following table shows the number of passengers, exclusive of season ticket holders, carried since the opening of the railway in each half-year:—

Half-year	Number of passengers.	Receipts (including season tickets).
Ended December 31, 1890 (11 days) about ...	165,000	£1,568 3 9
„ June 31, 1891 ...	2,412,343	19,403 6 9
„ December, 31, 1891 ...	2,749,055	19,798 16 6
„ June 30, 1892 ...	2,813,162	20,931 4 2
„ December 31, 1892 ...	3,217,602	22,002 17 5
Total since the opening of the line ...	11,357,162	83 704 8

By the appended certificate of the engineer, it will be seen that the locomotives, rolling stock and generating plant have been efficiently maintained and are in good working order. Difficulties with the local authorities have delayed the commencement of the much-needed siding accommodation at Stockwell station, forming part of the Clapham extension line, but it is hoped that these works will very shortly be started. The conversion of the terminal debentures into either Four per Cent. Perpetual Debenture Stock, or Five per Cent. Perpetual Preference shares is progressing satisfactorily, and will result in a considerable saving of interest to the Company.

A resolution for the conversion into consolidated ordinary stock of the remaining 3,000 ordinary shares already issued, will be submitted to the special meeting, to be held at the conclusion of the half-yearly meeting.

It is anticipated that the Bill promoted in the last Parliament by this Company for the extension to Islington and other purposes, will be proceeded with immediately after Parliament assembles. A Bill to extend the time for the purchase of lands under the Act of 1890 (Clapham Extension) and for other purposes, has been deposited in Parliament for this Session.

The Directors retiring by rotation are Messrs. Charles Seymour Grenfell and Edwin Tate, who are eligible for re-election. The auditors retiring are Messrs. Turquand, Youngs, Weise, Bishop, and Clarke, and they offer themselves for re-election.

Anglo-American Telegraph Company (Limited).

The following report of the Directors of this Company will be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, E.C., to-morrow (Friday), at 2 o'clock:—

The total receipts from July 1st to December 31st, 1892, including the balance of £954. 17s. 11d. brought forward from the last account, and a sum of £1,619. 16s. 9d. transferred from the Interest of Renewal Fund Securities, amounted to £164,365. 11s. 3d. This sum, however, is subject to revision, as the law suit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal. The traffic receipts show a decrease of £4,670 as compared with the corresponding period of last year, but the total for the year 1892, as compared with 1891, shows an increase of £5,365.

The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £58,628. 7s. 6d.

Interim dividends of 12s. 6d. per cent. on the Ordinary Stock and £1. 5s. per cent. on the Preferred Stock, were paid on November 1st last, absorbing £43,750, leaving a balance of £61,987. 3s. 9d., out of which the Directors recommend the proprietors to declare final dividends of 17s. 6d. per cent. on the Ordinary Stock, and £1. 15s. per cent. ou the Preferred Stock, amounting to £61,250, making a total distribution for the year ended December 31, 1892, of £2. 15s. per cent. on the Ordinary Stock, and £5. 10s. per cent. on the Preferred Stock, leaving £737. 3s. 9d. to be carried forward to the next account.

The Company s repairing S.S. "Minia" has been engaged during the past half-year in the repair of the North and South Placentia Cables, and the Duxbury Cable. She has also been employed by the Direct United States Cable Company, and the Western Union Telegraph Company for the repair of cables belonging to those Companies, the payments for which appear in the revenue account. The Brest-St. Pierre Cable was broken on July 14th, and repaired on August 5th by the Telegraph Construction and Maintenance Company's S.S. "Britannia," the S.S. "Minia" not being at the time available to undertake the work as an entire renewal of her decks had become necessary.

The Company's cables and land lines are in good working order and condition.

The appeal in the proceedings between the Anglo Company and the Par and New York Telegraph Company, in the Appeal Court of Paris, has no yet been heard

BOOKS FOR ELECTRICIANS, ELECTRICAL ENGINEERS, AND OTHERS.

The following Standard Electrical Works are sent post free to any address at the prices quoted :—

THE "ELECTRICIAN" SERIES.

IN TWO VOLUMES.

THE ALTERNATE CURRENT TRANSFORMER IN

THEORY AND PRACTICE. By J. A. FLEMING, M.A., D.Sc. (Lond.), Professor of Electrical Engineering in University College, London, &c., &c.

Vol. I., *500 pages, 157 illustrations. Third Issue, price 7s. 6d., post free (U.K.); abroad, 8s. 2d., post free.*

Synopsis of Contents.—Chapter I. Introductory.—Chapter II. Electro-Magnetic Induction.—Chapter III. The Theory of Simple Periodic Currents.—Chapter IV. Mutual and Self Induction.—Chapter V. Dynamical Theory of Current Induction.

Vol. II., *over 600 pages, and more than 300 illustrations. Price 12s. 6d., post free.*

Synopsis of Contents.—Chapter I. The Historical Development of the Induction Coil and Transformer.—Chapter II. Distribution of Electrical Energy by Transformers.—Chapter III. Alternate-Current Electric Stations.—Chapter IV. The Construction and Action of Transformers.—Chapter V. Further Practical Applications of Transformers.

370 pages, 159 illustrations, price 10s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER

METALS. By J. A. EWING, M.A., B.Sc., &c.

After an introductory chapter, which attempts to explain the fundamental ideas and the terminology, an account is given of the methods which are usually employed to measure the magnetic quality of metals. Examples are then quoted showing the results of such measurements for various specimens of iron, steel, nickel, and cobalt. A chapter on Magnetic Hysteresis follows, and then the distinctive features of induction by very weak and by very strong magnetic forces are separately described, with further description of experimental methods, and with additional numerical results. The influence of Temperature and the influence of Stress are next discussed. The conception of the Magnetic Circuit is then explained, and some account is given of experiments which are best elucidated by making use of this essentially modern method of treatment. The book concludes with a chapter on the Molecular Theory of Magnetic Induction; and the opportunity is taken to refer to a number of miscellaneous experimental facts, on which the molecular theory has an evident bearing.

The same book in German, price 8s. 6d., post free.

320 pages, 155 illustrations, price 6s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS.

LAWS, UNITS, AND SIMPLE MEASURING INSTRUMENTS. By A. E. KENNELLY and H. D. WILKINSON, M.I.E.E.

Fully illustrated, price 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF

METALS. (Theoretical and Practical.) By Dr. GEORGE GORE, LL.D., F.R.S.

No other book entirely devoted to the Electrolytic Separation and Refining of Metals exists in any language; those on Electro-Metallurgy hitherto published being more or less solely devoted to electro-plating. The present book contains both the science and the art of the subject, *i.e.*, both the theoretical principles upon which the art is based, and the practical rules and details of technical application on a commercial scale, being thus suitable for both student and manufacturer.

Price 3s. 6d., post free.

THE STEAM-ENGINE INDICATOR AND INDI-

CATOR DIAGRAMS. Edited by W. W. BEAUMONT, M.I.C.E., M.I.M.E., &c.

A Practical Treatise on the Steam-Engine Indicator and Indicator Diagrams, with Notes on Steam Engine Performances, Expansion of Steam, Behaviour of Steam in Steam Engine Cylinders, and on Gas Engine Diagrams.

Second Edition, price 2s., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE, LL.D., F.R.S.

Price 2s. 6d., post free.

DIGEST OF THE LAW OF ELECTRIC LIGHTING.

By A. C. CURTIS HAYWARD, B.A., A.I.E.E. An abstract of the Electric Lighting Acts, 1882 and 1889, and of the various documents emanating from the Board of Trade dealing with electric lighting. The digest treats first of the manner in which persons desirous of supplying electricity must set to work, and then of their rights and obligations after obtaining Parliamentary powers; and gives in a succinct form information of great value to Local Authorities, Electric Light Contractors, &c. Revised up to January, 1893.

In Two Volumes—Price: stout paper covers, 2s., post free 2s. 2d. each; strong cloth, 2s. 6d., post free 2s. 9d. each. Single Primers, 3d., post free 3½d.

"THE ELECTRICIAN" PRIMERS. Fully illustrated.

A Series of Helpful Primers on Electrical Subjects.

TABLE OF CONTENTS:

Volume I.—THEORY.

Primer No.
1. The Effects of an Electric Current.
2. Conductors and Insulators.
3. Ohm's Law.
4. Primary Batteries.
5. Arrangements of Batteries.
6. Electrolysis.
7. Secondary Batteries.
8. Lines of Force.
9. Magnets.
10. Electrical Units.
11. The Galvanometer.
12. Electrical Measuring Instruments.
13. The Wheatstone Bridge.
14. The Electrometer.
15. The Induction Coil.
16. Alternating Currents.
17. The Leyden Jar.
18. Influence Machines.
19. Lightning Protectors.
20. Thermopiles.

Volume II.—PRACTICE.

Primer No.
21. The Electric Telegraph.
22. Automatic and Duplex Telegraphy.
23. The Laying and Repair of Submarine Cables.
24. Testing Submarine Cables.
25. The Telephone.
26. Dynamos.
27. Motors.
28. Transformers.
29. The Arc Lamp.
30. The Incandescent Lamp.
31. Underground Mains.
32. Electric Meters.
33. Electric Light Safety Devices.
34. Systems of Electric Distribution.
35. Electric Transmission of Energy.
36. Electric Traction.
37. Electro-Deposition.
38. Electric Welding.

The object of "The Electrician" Primers is to briefly describe in simple and correct language the present state of electrical knowledge. Each Primer is short and complete in itself, and is devoted to the elucidation of some special point or the description of some special application. Theoretical discussion is as far as possible avoided, the principal facts being stated and made clear by reference to the uses to which they have been put. Both volumes are suited to readers having little previous acquaintance with the subject. The matter is brought up to date, and the illustrations refer to instruments and machinery in actual use at the present time.

ADDITIONAL VOLUMES IN PREPARATION.

A POCKET BOOK OF ELECTRICAL ENGINEERING

FORMULÆ. By W. GEIPEL and H. KILGOUR. *[In preparation.*

With the extension of the heavier branches of Electrical Engineering the need of a publication of the Pocket-Book type dealing therewith increases; for while, on the one hand, there are many such referring to Mechanical Engineering, and, on the other hand, several which deal with Electrical Rules and Formulæ as more particularly applied to the lighter branches of Electrical Engineering, yet none of these alone suffice for the purposes of what may now be said to be the more numerous body of Electrical Engineering, viz.: those engaged in the application of Electricity to lighting, transmission of power, metallurgy and chemical manufacturing. It is to supply this want that this book has been prepared.

SUBMARINE CABLE-LAYING AND REPAIRING.

An Original Work on this important subject, which has not previously been treated in a thoroughly practical manner. By H. D. WILKINSON, M.I.E.E., &c., &c. Fully illustrated. *[In preparation.*

ELECTRO-MAGNETIC THEORY. By OLIVER HEAVISIDE.

[In preparation.

DRUM ARMATURE WINDING & COMMUTATORS:

IN THEORY AND PRACTICE. By F. M. WEYMOUTH. *[In preparation.*

A complete treatise of the theory, and the different methods of construction of Drum Winding, and also of close-coiled continuous-current Commutators, together with a full resumé of some of the principal points of consideration that are involved in their design.

ELECTRICITY AS A MOTIVE POWER. By ALBION

T. SNELL, Assoc. M. Inst. C.E., M.I.E.E. *[In preparation.*

ELECTRIC LIGHT: ITS PRODUCTION AND USE. By J. W. Urquhart. Fifth Edition, carefully revised, with large additions. Price 7s. 6d., post free (U.K.)

New Edition, 640 pages, 307 illustrations, price, cloth gilt, 10s. 6d., post free.

ELECTRICAL ENGINEERING FOR ELECTRIC LIGHT Artizans and Students. By W. Slingo and A. Brooker.

Second Edition. 358 pages, 126 illustrations, price, cloth gilt, 7s. 6d., post free.

ELECTRIC TRANSMISSION OF ENERGY. AND ITS TRANSFORMATION, SUBDIVISION, AND DISTRIBUTION. By Gisbert Kapp, C.E. A Practical Handbook

67 illustrations, price 6s., post free.

PRIMARY BATTERIES. By H. S. Carhart, A.M. Giving descriptions of the Construction, Working, and Testing of a large number of Primary Batteries, with Introductory Chapters on Theory.

Price 6s. 6d., post free.

A COMPREHENSIVE INTERNATIONAL WIRE TABLE. By W. S. Boult. Giving full particulars of 469 Conductors (4 gauges), Single Wires and Cables, in English, American, and Continental Units.

Fifth Edition, carefully revised, price 1s., post free.

THE ELECTRIC LIGHT POPULARLY EXPLAINED. By A. Bromley Holmes, M.INST.C.E.

Fourth Edition, revised and enlarged.
Cloth, 864 pages, 29 folding plates, 498 illustrations in text, 24s. post free.

DYNAMO-ELECTRIC MACHINERY: A TEXT-BOOK FOR STUDENTS OF ELECTRO-TECHNOLOGY. By Silvanus P. Thomson, B.A., D.Sc., M.I.E.E., F.R.S.

This edition has been very largely re-written, and contains several features distinguishing it from its predecessors. Detailed descriptions are given of the large dynamos used in central stations, and chapters are added on alternate-current motors, on the theory of armature winding, on the construction of armatures, commutators, &c., and on electrical transmission of power.

New and greatly enlarged Edition. Quarto, 300 pages, 275 illustrations, 12s. 6d., post free 13s. 6d.

THE ELECTRIC MOTOR AND ITS APPLICATIONS. By T. C. Martin and J. Wetzler.

A POCKET BOOK OF ELECTRICAL RULES AND TABLES, FOR THE USE OF ELECTRICIANS AND ENGINEERS. By John Munro, C.E., and Andrew Jamieson, C.E., F.R.S.E. Pocket size, leather. Ninth Edition, revised and enlarged, with numerous Diagrams. 8s. 6d.

With 227 illustrations, 3s. 6d., post free.

THE PRACTICAL TELEPHONE HANDBOOK AND GUIDE TO TELEPHONIC EXCHANGE. By Joseph Poole, Chief Electrician to the late Lancashire and Cheshire Telephonic Exchange Company, Manchester.

Fully illustrated, price 11s., post free.

THE ELECTRIC RAILWAY IN THEORY AND PRACTICE. By Oscar T. Crosby and Louis Bell.

This is the only *original* work on The Electric Railway published in any language. Other books are chiefly extracts from this valuable work.

Price—Paper, 1s., post free; mounted and glazed, 1s. 6d., post free; in neat cloth case for pocket, 2s. 6d., post free; mounted and glazed and bound in cloth for pocket, 2s. 6d., post free.

THE WOODHOUSE AND RAWSON WIRING TABLES. Printed Directions how to use the Tables are issued with each Copy.

For the Pocket. Price 2s. 6d.; post free, 2s. 7d

THE WIRING SLIDE-RULE (TROTTER'S Patent).

By which can be found at once:—1. Size of Cable; 2. Length of Cable; 3. Cur Cable will carry; 4. Current Density; 5. Maximum Current; 6. Resistance Ohms; 7. Sectional Area in Square Inches.

Full Printed Instructions are supplied with each Rule.

Pocket Size, price 2s. 6d., post free 2s. 8d.

MAY'S POPULAR INSTRUCTOR FOR THE MANAGEMENT OF ELECTRIC LIGHTING PLANT. An indispensable handbook for persons in charge of Electric Lighting plants and more particularly those who have had little or no technical training.

For office use, printed on cardboard, with metal edges and suspender, price 2s. each post free 2s. 2d. For the pocket, mounted on linen, in strong case, 2s. 6d. each, post free, 2s. 8d.

MAY'S TABLE OF ELECTRIC CONDUCTORS.

MAY'S BELTING TABLE.

HULL CORPORATION.

ELECTRIC LIGHT WORKS.

TO IMPROVERS.

The Corporation are prepared to take TWO IMPROVERS into their Electric Light Works, for a period of two years, at a premium of £30.

Candidates must have had some experience in Engineering Workshops, and possess certificates from the Electrical Engineering Department of some Technical School.

Applications in which candidates' ages must be stated, accompanied by copies of the necessary certificates to be endorsed "Improvers for Electric Light Works," to be delivered to me on or before 10 a.m. on THURSDAY, February 9th next.

F. HARMAN LEWIS, Borough Electrical Engineer.

Electric Light Station, Hull.

PUPIL.—Electrical Engineer in Ireland has an OPENING for PUPIL. Experience in erection, main laying, station running, testing house wiring. Moderate fee required.—Apply, stating age, &c., No. 1,163, *Electrician* Office, Salisbury Court, Fleet Street, E.C.

VACANCY FOR PUPIL.—An opportunity occurs for a well educated and intelligent Youth with some knowledge of Electrical Work as PUPIL in a Consulting Electrical Engineer's Office, where facilities for varied Experience would be obtainable. Premium, One Hundred Guineas per annum for two years.—Address "M. Z.," care of Street & Co., 30, Cornhill, E.C

WANTED, a TRAVELLER or CANVASSER, who has a good connection in firms dealing in Electrical Machinery, Instruments, &c., to obtain Advertisements for a Journal which has a world-wide circulation. Good payment.—For particulars apply to B., 360, S. HAASENSTEIN & VOGLER, Bureau Spécial, Switzerland, Berne.

WIREMAN WANTED. Must be well up in making vulcanised joints, overhead work, house wiring, and dynamo running. Permanent job to good, steady man. Give full particulars of experience; wages.—No. 1162, *Electrician* Office, Salisbury Court, Fleet Street.

ELECTRICAL ENGINEER (22) desires SITUATION as ASSISTANT ENGINEER in Central Station, or Manager's Assistant with Firm. Thorough workshop and theoretical training (A.I.E.E.) Good references.—"PHASE," *Electrician* Office, Salisbury Court, Fleet Street, E.C.

ELECTRICIAN (19½) desires SITUATION. Competent to assist in erecting Lighting Installations and preparing plans for same. 3 years' experience, excellent testimonials.—P. PASK, 23, Mawson Road, Cambridge.

ENGINE DRIVER, &c., wants EMPLOYMENT used to Dynamos, Motors, Accumulators. Well up with traction work.—GODWIN, 56, Stanmer Street, Battersea.

MECHANICAL and ELECTRICAL ENGINEER (29) desires SITUATION in South Africa; good draughtsman; three years in Science College Whitworth Scholar—Apply 9, Gatefield Street, Crewe.

WANTED, SITUATION as ASSISTANT DRAUGHTSMAN in Electrical Works. Good experience and references. 2½ years at Woodhouse & Rawson's.—R. RAE, 34, Riversdale Road, Highbury, N.

CROSBY INDICATOR.—Nearly new, in teak case, with 30-lb. spring and accessories. Price, £7 nett.—Address, 1165, *Electrician* Office, Salisbury Court, Fleet Street, E.C.

FOR SALE.—A number of ORNAMENTAL IRON STANDARDS for overhead-wiring or street-lighting.—Apply, EXETER ELECTRIC LIGHT CO., LTD., Exeter.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.

Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 768.—Vol. XXX. FRIDAY, FEBRUARY 3, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The necessity for a comparison between the suggestions put forward by the Committee of the Electrical Section of the Royal Commission for the Chicago Exhibition, and the recommendations of the sub-committee of the American Institute of Electrical Engineers as to the programme for the forthcoming Electrical Congress is not necessary, since the former were proposed in a very tentative fashion, and aimed at little else than a string of ideas from which programme makers might derive assistance. The provisional programme, of which we print an abstract in another column, contains some useful recommendations, and displays a good knowledge of the subjects with which it deals, as well as of the needs of the hour. That a set of definitions of physical quantities for international use should be contributed from America to Europe is a sign of the times; and whether the programme be adopted or no, or whether even any Congress be held at all, we welcome this report as an interesting landmark in the development of real American science.

The first definition is not well worded. If the impressed electromotive force is the ratio of the electrical activity to the instantaneous value of the current, what happens after the removal of the electromotive force acting in a circuit possessing self-induction? The activity of the circuit is at first unchanged, since the current is not altered instantly, so that, according to the definition, the electromotive force is the same as before. It is true that the dying magnetism supplies the electromotive force needed for maintaining the current, but this is not in any sense impressed upon the circuit, for the circuit itself supplies it. It would have been better to merely reproduce the definition, adopted by the Board of Trade Committee, for the volt, namely, the potential difference needed to drive a current of one ampere through one ohm.

Some definitions are given of quantities which are at present hardly ever used. Who wants a unit of reluctivity; and, if there be such a person, is he likely to receive any help from the definition that "the reluctivity of a medium at any point is the volume differential of the reluctance thereat"?

With the practical parts of the report we have more sympathy than with the theoretical. Among the terms which are recommended for universal use we are glad, and indeed surprised, to find that no change whatever is needed in the language commonly used in the editorial columns of this journal. "Voltage" is recommended as synonymous with the ponderous pedantry of "difference of electrical potential," with the slovenly "potential," with the slang "P.D.," or the far worse "E.M.F.," with the antiquated "tension," and with the often unscientific but sensible term "pressure." But our experience goes to show that, if only on account of tautology, the term "voltage" will not always suffice. Again, the use of "transformer" for "converter" has for long been our custom, and "dynamotor" for "continuous current transformer" for a necessarily shorter period. "Continuous current" is preferable to "direct current," but this is not a matter of importance.

In the same breath, however, the report recommends the use of "kilowatt" for horse-power. This is an altogether different matter, and one to which, if a real substitution is intended, we strongly object. For heaven's sake let those who have to employ the term be engineers first and electricians afterwards! We should much prefer to stick to I.H.P., B.H.P., and E.H.P., and let the kilowatt go by the board, if there need be a choice. But there is none; the kilowatt has its uses. While such reforms are going on, we should like to see the affected and pompous term "installation" abandoned. Engineers got on perfectly well with "plant," or "job," or "work," before they were corrupted by the accident of an exhibition at Paris. We find no difficulty in excluding "installation" from our editorial columns.

Of the seven names for units which are put forward, a majority stand a good chance of adoption at the Congress. The "mho" has been laughed at, but we are probably justified in saying that no one who uses units of conductivity employs any other name; but the same might be said for the use of the name "haf" as the reciprocal of a degree Fahrenheit. The "henry" is sure to be received, for it has been already well tried and only once stood in danger of becoming ridiculous when "milli-hens" and the like were suggested. The "œrsted" for magnetic reluctance and the "gilbert" for magneto-motive force are of rather doubtful value, but we hope that the pair of names, the "gauss" and the "weber," will be respectively adopted for what the report calls "the practical unit of magnetic intensity," presumably **B**, and for total lines of force or **N**. The much needed unit of illumination is likely to give rise to some discussion, the "bougie-metre" or the

Hosted by Google

"candle-foot" are open to the objection that all other such compound names imply a product of the components, while in this case the former component is divided by the square of the latter, or is multiplied by the square of its reciprocal. We might then have "candle-toof.toof," on the "mho" principle, a term accurate enough to satisfy even M. Hospitalier, and hardly more uncouth than "mega-barads," "microboles," and "kilogramme-kines," which have been proposed without apology.

It would not be amiss if the Council of the Institution of Electrical Engineers were to allot an evening or two to a discussion of these proposals, the speakers being kept rigidly to the subject before the meeting, namely, the adoption, rejection, or moderate amendment of America's contributions to international electrical nomenclature. No good can come at this time of day from airy schemes for revolutionising our system of units, or from fads for increasing this practical unit by one-tenth and decreasing another to the same extent to make a fit. At the close of the debate the Council might perhaps reduce the general sense of the meeting to concrete resolutions which might be put to the vote of members only.

In another column we print an article by J. E. Moore, describing some measurements of the losses occurring in iron when subjected to alternating magnetic forces. The method adopted is a modification of Dr. Duncan's dynamometer method of analysing alternate current curves, the only change being that the alternating magnetic field caused by the current in the fixed coil of the dynamometer is replaced by the magnetic field whose variations are being investigated. The results are of great interest; but the method is a needlessly roundabout way of obtaining data from which to estimate the core losses of transformers. A much quicker and simpler method consists in winding a coil around the iron samples, and measuring with an ordinary wattmeter the power absorbed by the solenoid for different voltages. The average induction density in the core can be obtained from the voltage, the current frequency, and the section of the core; and the watts wasted per unit volume of the core can, of course, be at once found. Not only is this obvious method simpler, but it is more accurate than that suggested by Mr. Moore, since, while the voltage absorbed by the coil is a measure of the average induction in the core, the deflection of Mr. Moore's magnetometer depends on the induction in the air outside the core, where magnetic leakage difficulties are greatest.

The refraction of electric waves by large prisms and lenses made of pitch has been investigated by Herz and others, the result found being that the refractive index for these waves is about the same as that obtained with optical measurements. There is no reason to expect a close agreement, owing to the great difference in frequency of the electric and optical waves, which in most cases causes the prism to produce a wide spectrum. When the angle of the spectrum is large it is impossible to verify Maxwell's prediction, that the specific inductive capacity of a substance is equal to the square of its index of refraction, since the latter quantity can only be determined optically with light waves of short wave length, while the law is only supposed to be true for long waves, such as those occurring in electric oscillations. Maxwell's law is accordingly found to be accurately true for some substances, while for others it does not seem to hold. The present instance is a remarkable case in which the law is applicable when measurements made with ordinary light appear to show that the law is wrong.

Herr Ellinger has recently measured the index of refraction of alcohol by passing a beam of electric waves through a large prism containing about nine gallons of a 95 per cent. solution of alcohol, and measuring the refraction produced. The index found is very high—4·9—but it appears to agree very fairly with theory, since the specific inductive capacity was measured at the same time, and was found to differ very little from $(4{\cdot}9)^2$. The index of refraction of this liquid for ordinary light is generally given as 1·37, and as violet light is more refracted than red, and red light more than dark radiation, it would be natural to expect that the index for electric rays would turn out to be less than 1·37 instead of more. A specific inductive capacity of nearly 25 is, moreover, very high. The result is, however, not impossible, and is of great theoretical importance if it be confirmed.

Although the law has for many years provided that an assessor *may* assist a judge in trying patent cases, and that an assessor *must* be found if either side make an application, no such procedure, so far as we know, has ever been witnessed in English law courts until this week. Hitherto each party has endeavoured to retain the best counsel and the cleverest witnesses, and has relied on hired wit to win the judge. A frank and candid explanation of the whole case before the judge is not made, for it is nobody's business to make it. The witnesses are of course prepared to give the "whole truth," but they can only answer questions. In the case of Paine *v.* Thompson, relating to a patent "cyclone" dust collector, invented by Prof. V. Boys, and used in flour milling, Prof. George Forbes is acting as assessor, Mr. Justice Wills being the judge. We are very glad to see the adoption of a course which has been consistently advocated in these columns. The next step should be the appointment of witnesses by the Court instead of by the parties, but we understand that the Bar is strongly opposed to this.

Up to the present we have not felt able to advocate the general use of electric motors in place of hydraulic gear or auxiliary steam engines on board ship, but the effect of the recent frost on the "Benbow" discloses a weak point in hydraulic machinery which has no parallel in electrical work. The gear of the heavy guns has been not only disabled, but has suffered such serious injury that it has been found necessary to take the greater portion of it to pieces, and to forward it to the manufacturers for reconstruction and repair.

Hosted by Google

At a late hour yesterday afternoon, and with some difficulty, we obtained a copy of the first Report of the Royal Commission on Electrical Communication with Lighthouses, and have made room for an abstract of it in another column. The recommendations contained therein will be gratifying to Sir Edward Birkbeck, Mr. Robert Bayley, and others, who have zealously advocated the cause of such electrical communication, and these recommendations are, we hope, the first instalment of a complete system.

Royal Institution.—On Saturday, February 18th, Lord Rayleigh will begin a course of six lectures on "Sound and Vibrations."

Personal.—Mr. W. Perren Maycock has commenced practice as consulting engineer, with offices at No. 96, George-street, Croydon.

Blackpool.—A Local Government Board Inquiry was held at Blackpool on Monday by General Crozier, R.E., into the application of the Corporation to borrow £26,000 for the purposes of electric lighting.

Tunbridge Wells.—At the meeting of the Town Council on Wednesday last Mr. Preece's report and recommendations with regard to the electric lighting of the town were received, but discussion on the subject was deferred for a month.

Cable Interruptions and Repairs—

Cable.	Interrupted.	Repaired.
Mozambique-Laurenço Marques ...	Jan. 25, 1893	Jan. 27, 1893
Cables actually interrupted.		
Cayenne-Vizeu	Sept 24, 1892	—
Senegal-Pernambuco	Dec. 26, 1892	—

Obituary.—The death is announced of Prof. J. Stefan, who presided over the International Scientific Committee of the Vienna Electrical Exhibition, and who carried out numerous researches on the propagation of sound, refraction, the polarisation and interference of light, the conduction of heat, &c.

Accumulator Cars in Berlin.—The Great Berlin Tramway Company has obtained permission to make experiments with secondary battery cars on one of its lines. It is intended to have the cars in service by May, and upon the result of the tests depends the granting of a concession for the establishment of a new tram line proposed to be worked by electricity.

Salford.—According to a statement made by the Chairman of the Gas Committee, the electric light installation in the central portion of the borough will cost more than £30,000, as originally stated. The Council have agreed that power should be asked to borrow £50,000 to meet the initial cost, and any extensions that may be necessary in the future.

Bolton.—The Gas and Lighting Committee have decided that application be made to the Local Government Board for sanction to borrow £40,000 for electrical purposes. The system to be adopted is to be the high pressure continuous current. Advertisements are to be inserted for an electrical engineer to advise on the proposed works, and to have charge of the construction, &c., at a salary of £200 per annum.

Electric Launches and the Merchant Shipping Act.—Lord Coleridge and Mr. Justice Charles last week quashed the conviction against the Southport Corporation for having an electric launch on the Southport foreshore lake for the conveyance of passengers without a certificate under the Merchant Shipping Act, 1854. Their lordships said it was absurd to think that a small electric boat on an artificial piece of water was ever intended to come within the Act.

Popular Lecturing Made Easy.—A correspondent informs us that a lecture was given in Edinburgh last week upon "The Electric Light in Our Homes." The title will be recognised as that of a book which has enjoyed an extensive circulation, if not a large sale. There is nothing remarkable in this, but we have received five sheets of manuscript in parallel columns containing extracts from the lecture and from the book side by side. They are for the most part word for word the same. We understand that no acknowledgment was made. It may be difficult to find something new to say about the advantages of electric lighting, but such plagiarism is insulting to the audience, discreditable to the lecturer, and shabby to the original author.

The Junior Engineering Society.—The eighth annual dinner of this Society was held on Saturday evening last at the Holborn Restaurant. The President, Dr. John Hopkinson, took the chair. Among those present were Sir George G. Stokes (vice-president), Sir Frederick Abel, Mr. W. H. White (vice-president), and Prof. John Perry (past president). Sir George Stokes, in reply to the toast of "Science and Technology," said some friends of his devoted themselves exclusively to abstract science, and even disliked the idea of its practical application. For himself, he thought that it could hardly be applied too much. The President of the Royal Society, Lord Kelvin, was one example of the advantages that came of that union of the two things.

The Telephone Companies.—The following *communiqué* appeared in the *Standard* of yesterday:—

> We have reason to believe that no foundation in fact exists for the doubt, expressed in the circular which has just been issued by the Association for the Protection of Telephone Subscribers, whether the agreements entered into by the New Telephone Company with that Association and with private individuals for the supply of telephones on its system upon advantageous terms are still binding since its so-called "amalgamation" with the National Telephone Company. Although provision has been made for the transfer of shares from one Company to the other, the New and National Telephone Companies have not been, in the strict sense of the word, "amalgamated," nor have the prior obligations of the New Telephone Company been extinguished. The objects of the recent arrangement between the Companies were to obviate friction and competition, and to facilitate the introduction of the improved system of telephony which the New Telephone Company was incorporated to promote, and no release of either of the Companies from any of its existing engagements was intended, or is in contemplation.

Union of German Electrical Engineers.—Under the title of the Verband der Elecktrotechniker Deutschlands, an association has just been constituted in Berlin. The members comprise the leading electrical firms, many scientific notabilities, and representatives of all the electrotechnical societies now scattered throughout Germany. The scope of the union is very varied, as in addition to being an electrical institution it will watch over the interests of the industry, and give reliable information concerning the views of electrical engineers. An instance quoted as showing the necessity of such an institution was the case of the recent Telegraph Act, and it is now intended that the union shall be of use in connection with the forthcoming legislation on electric light and power industries. All those either directly or indirectly interested in the different branches of electrical applications, and particularly industrial customers and municipal and other administrations, will be invited to join the union, which is to hold its first annual assembly in August or September next.

Light, Paper, and Eyesight.—An endeavour has been made to tint the paper of the latest evening journal in London to enable it to be read with comfort in a bad light. The tint which has been selected is green, but rays of this colour are not present in abundance in most artificial lights. As a result, with a bad smoky flame, the paper seems to be of a dirty grey colour, and were it not for the excellent quality of the paper and type, it would be very difficult to read. Under an arc lamp the green colour shows up, and we have found an unexpected difference in this respect between ordinary gas light and that of a good glow lamp. The best colour for the paper would be that in which artificial light is most rich, namely, yellow or orange—though there may be political reasons against the latter. The new journal, which is to be congratulated on having already received as a "short title" *The Gazette*, has made, at all events, a praiseworthy, though, we think, mistaken attempt to diminish eye-strain in this manner. We have further to congratulate the *Westminster Gazette* on being, so far as we know, the only daily newspaper besides *The Times*, which contains no advertisements of Harness' belts.

Storage Battery v. Overhead Trolley Cars in Boston.—What promises to be a bitter fight, says the *Street Railway Gazette*, is now inaugurated between the West End Street Railway Company and a concern calling itself the Cambridge

Hosted by Google

Storage Battery Street Railway Company. The latter Company has petitioned for the privilege to run cars operated by storage batteries on the tracks of the West End Company, and thereby secure an entrance into the city of Boston. The law in the case is peculiar, and seems to protect the rights of both parties. In the first place there is a provision in the statutes that the lines of any one company may be used by any other company operating two miles or more of track. The reason for this is to afford better transportation for the public. Under this regulation it would seem that the Battery Company had a right to use the tracks of the West End Company; but the West End people were far-sighted enough to secure a clause in their original franchise which states that "no other street railway company shall operate on the lines of the West End Company without first securing the permission of the Board of Railway Commissioners." The matter will be taken into the Legislature, and what promises to be a very bitter fight is now well started.

York.—At the last meeting of the Town Council the minutes of the Streets and Buildings Committee, acting as the Electric Lighting Sub-committee, came up for adoption; and, according to the *Yorkshire Gazette*, the following discussion took place:—

Alderman Wragge asked if Mr. Crompton drew up the specifications for the electric lighting scheme, and whether he had tendered for the execution of the work on his own specifications. Further, he desired to know what were the services rendered by Mr. Crompton when he acted as consulting electrical engineer to the Corporation, and whether, when engaged, he gave an assurance that his own firm would not tender for the carrying out of the work?—Mr. Purnell inquired what proof they had that Prof. Kennedy, of Westminster, whom it was proposed to now engage as the engineer, had no partiality for any particular system or combination of systems—that he had no business connection with any electric lighting contractors; whether there was such a company as the City of London Electric Lighting Company; whether Professor Kennedy had carried out any work at all excepting the Westminster Supply Corporation's work?—Alderman Agar said it was true that the specifications were drawn up by Mr. Crompton, but they were very wide and not tied to any system. Mr. Crompton was released from his engagement to the Corporation in order that the Company to which he belonged might tender. With regard to the question whether Prof. Kennedy had any connection with any electric lighting contractors, they had his own word for it that he was not.—The report was adopted.

Earthing the Middle Wire.—Another argument in favour of earthing the middle wire of a three-wire system comes to hand from Berlin. In October, 1890, the electric lighting company laid down a length of about one mile of main with the neutral wire grounded, but were obliged to insulate it at the request of the telephone officials. Recently, however, numerous tests carried out by the electric light and telephone engineers have shown that earthing the neutral is beneficial rather than otherwise, so far as the single-wire telephone system is concerned. The Berlin telephone officials have suffered considerably from leakage currents emanating from the lighting circuits, the most marked feature of the disturbances being the letting down of the exchange annunciators. The tests consisted in producing faults on the lighting mains with and without the neutral being earthed, and noting the number of annunciators affected. In the first experiment 7,799 annunciators were disturbed when the neutral wire was *not* grounded, and 3,524 when it was grounded. Omitting Exchange V., where the neutral was earthed at the same spot as the exchange wires, the relative figures with the neutral insulated, and with it earthed, were 4,189 and 241.

Brighton.—Mr. T. Codrington, one of the Local Government Board Inspectors, held an inquiry on Tuesday into the application of the Corporation for sanction to borrow £37,700 for purposes of electric lighting. The Town Clerk and the Deputy Town Clerk represented the Corporation, and Mr. Hugh Verrall attended to express the views of a number of consumers of the light supplied by the Hammond Company, who feared they might be prejudiced by the action of the Town Council. Some difficulty was found in supplying the Inspector with figures and plans as to work done under the last loan, and attention was also drawn to an overdraft on capital account of £5,880. Eventually the inquiry was closed, subject to further information being forwarded to the Inspector. Mr. Arthur Wright, electrical engineer to the Corporation, in the course of his evidence, stated that it was proposed to change over from the two-wire to the three-wire system, but that it was not proposed "to pay a royalty to Dr. Hopkinson, as they were not using his system!" Mr. H. M. Stevens, Borough Accountant, stated that the total amount spent on the Electricity Works up to December 31st, 1892, was £46,884; the amount borrowed being £41,000. By the time the present loan is exhausted the Brighton Corporation will therefore have spent something like £80,000 on electric lighting.

The Three-Wire System.—A correspondent writing from Portugal, under the date January 24th, calls attention to the evidence given in the recent patent case about the brightening up of lamps on one side of the middle wire when the other side was short circuited. He says that, excepting Mr. Swinburne, the experts questioned on this point agreed that the brightening up of one side with the other short circuited proved that the system was *not* the three-wire system, *i.e.*, that the middle wire was not actually connected to the dynamo. Our correspondent says that anyone who has run a three-wire station, and intelligently observed what occurs, knows that this is wrong. "Let the positive side be loaded up until the differential current flowing through the middle wire causes a fall of two volts in that wire. The lamps on the positive side will only get 98 volts. That is to say, the middle wire will be two volts more positive at the feeding point. Therefore the lamps on the negative side will get 102 volts, and will be perceptibly brighter. Or to put it in another way, part of the excess current goes back by the lamps on the negative side." As the Court was not satisfied that there was evidence to show that the middle wire at the Sauchiehall Works was connected to the dynamo, we do not think that a discussion on this point is useful, so far as the case is concerned, but granting that a connection existed, it must be remembered that the dynamo was an alternator. It is extremely difficult and quite useless to argue about what would have happened, considering the complications which would be introduced by the armature reactions of old-fashioned machines. The result would probably be very different from that which would take place with the ordinary three-wire system.

The Need for Electrical Communication Between Lightships and the Shore.—Captain Knox, Captain Cosens, and Captain Bigley, Nautical Assessors, had a case recently before them which furnished a remarkable illustration of the need of electrical communication between lightships and the shore. It was an inquiry into the loss of the steamship "Dilsberg," on the Longsand in the Thames estuary, on December 9th last. Six of the crew were drowned, and the captain sustained injuries which terminated fatally. The "Dilsberg" got aground between noon and one o'clock, seven miles from the Longsand light, nine to ten miles from the Kentish Knock, and about seven miles from the Sunk. Blue lights were burned and rockets fired for assistance, but they did not appear to have been observed. At about midnight the steamer settled down. At daylight on the 10th, the weather having moderated a little, the port lifeboat was patched up and lowered into the water, and at about 10 a.m. the fifteen survivors got into it and pulled towards the Kentish Knock lightship, which was reached at about four o'clock. The master of the lightship commenced at 5.18 to fire signals for assistance. He continued firing for a considerable time, but it was not until 6.12 that he got an answer from the Longsand. The captain of the Longsand lightship, seeing the flash of a rocket thought it was a signal of distress from a vessel which he had observed in the morning apparently at anchor. He thereupon signalled to the Sunk lightship to that effect, and thought he was answered by a lightvessel fourteen miles in another direction. The weather was undoubtedly more or less foggy at the time, but it was clear that the prescribed signals of these lightvessels were either not seen or were misunderstood, and the assistance required by the Kentish Knock lightvessel was therefore not forthcoming. There had, said the Board of Trade solicitor, unquestionably been a failure on the part of the particular lightships in question in communicating with one another, and it was the desire of the Board of Trade that the whole of the circumstances should be fully investigated. The survivors from the "Dilsberg" were taken off the lightship on the morning of the 11th by the smack "Cordelia" and landed at Ramsgate.

THE DIFFUSION OF LIGHT.

BY W. E. SUMPNER, D.SC.

The important part played by diffused light in general illumination is but little realised. It is well known that the great majority of bodies would be invisible if it were not for the diffused light scattered from their surfaces; but few seem to understand the great extent to which the illumination of rooms and open spaces is increased by the repeated reflections to which the light is subjected at the different diffusing surfaces it meets with before it is finally absorbed by bodies in the neighbourhood. In many cases of artificial lighting the illumination due to diffusion is four or even five times as important as that part of it which is due to the direct rays proceeding from the light sources within the enclosure considered; while, of course, daylight, although primarily all due to the sun, is in most cases almost entirely caused by rays which have suffered many reflections from clouds, or walls, or other diffusing surfaces.

Diffusion is, moreover, of importance in quite another way, for it alters the character of the illumination, and makes it much more pleasant for the eye to endure. The illumination at the base of an ordinary arc lamp at night-time is not nearly so strong as that of diffused daylight, yet it is much more tiring to the eye to look at an arc lamp in the street, although it may be surrounded with a good diffusing globe, than it is to look at a bright cloud on a summer's day. From measurements made by Mr. Trotter it appears that the maximum illumination on the pavement of Queen Victoria-street at night-time due to the arc lamps there is a little over one-half of a candle-foot [*i.e.*, the illumination caused by a standard candle at a distance of one foot], while the illumination of daylight on a bright day in London often exceeds 30 candle-feet. It thus appears that the eye can bear with comfort sixty times as much light from a diffusing surface, such as that formed by the clouds, as it receives when in the close neighbourhood of an arc lamp. But no one could long bear to look at 60 arc lamps at a distance equal to the height of an ordinary street lamp. This is not due in any way to the fact that the light is caused electrically in an arc lamp, since the general result is true of all artificial lights, and is due to the concentration of the rays on a particular part of the eye when proceeding from a small luminous area of great brightness. The dazzling effect of bright surfaces on the eye is not only unpleasant, but it causes the pupil to close up to a greater or less extent, and, as the amount of light received by the eye depends not only on the intensity of the illumination of the bodies viewed, but also on the area of the exposed portion of the eye, it is clear that any influence which causes a partial closure of the pupil of the eye produces the same effect as if the surrounding illumination were diminished. In estimating the usefulness of surrounding a naked arc with a good diffusing globe we must take into account both the absorbing power of the globe and the increased exposing power of the eye. If the globe absorbs 30 per cent. of the light of the arc, but at the same time so diffuses the light that the pupil of the eye increases in diameter by 20 per cent., and the area of the eye exposed by 40 per cent., the amount of light received by the eye is actually increased and not diminished by using the globe. This effect of diffused light on the eye is obviously of importance; yet no experiments appear to have been made on the subject, perhaps because they are rather hard to carry out. Until such experiments are made it is impossible to say to what extent this effect takes place; but the general taste for the use of opal globes, and other diffusers, has probably some solid foundation not yet completely understood; and the mere fact that such globes often absorb 30 or 40 per cent. of the light produced within them is not so important as is often imagined. One of the most useful properties of diffused light is that it does not cast shadows. However powerful may be the arc lamps lighting an area, the illumination never appears good if there are sharp shadows about. A photometer may declare that the average illumination is high, but the eye is the sole judge in these matters, and refuses to be satisfied. In an ordinary room, with walls covered with paper of average reflecting power, the illumination due to reflection from the walls is fully as important as that due to the direct rays of the lamp or lamps within it, and this diffused illumination, instead of varying with the distance from the lamp, is constant all over the room, casts no shadows, and is as well diffused as ordinary daylight.

In order now to get an estimate of the extent to which the action of the walls of a room increases the illumination, let us suppose that the lights within the room add up 100 candle-power, and that the average reflecting power of the walls, ceiling, &c., is 50 per cent. Then, of the light which is incident on the surface of the room, 50 per cent. is reflected back into the room again, and as this light is just the same as any other light, it is equivalent to an additional light of 50 candle-power. The rays from this second light strike the walls again, and those which are reflected anew form a third light of 25 candle-power, and so on. The sum of the series 100, 50, 25, $12\frac{1}{2}$, &c., is equal to 200, so that the effect of the walls is just as if the lamps within the room were of 200 candle-power instead of 100. Similar reasoning shows that if the walls and ceiling reflected 80 per cent. of the incident light, the illumination within the room will be as if the candle-power of the lamps, instead of being 100, were 500, and of this illumination that portion due to the walls is four times as important as that due to the direct rays of the lights. Such a result is quite possible to realise with well whitewashed surfaces. If we take an extreme case, and suppose that the walls, &c., are covered with mirrors reflecting about 92 per cent. of the light incident upon them, the equivalent candle-power within the room would be increased in the ratio of 8 to 100, or from 100 candle-power to 1,250, that is more than twelve times.

Light is, in fact, heat energy in a special form, and if it is produced at a regular rate by some light source within any enclosure, the amount of light within this space must go on increasing until the walls absorb the light as fast as it is produced by the sources. Thus, if Q be the quantity of light produced per second by the lamps, and Q′ be the quantity falling per second on the walls, we must have

$$Q' = Q + r\,Q',$$

where r is the average reflecting of the walls. For Q′ must consist of two parts, that which is absorbed by the walls, and that which is reflected. By definition $r\,Q'$ must be the latter quantity, and the former is equal to Q for the reason just stated.

Hence,
$$Q' = \frac{1}{1-r}\,Q,$$

and the increase of illumination by reflection must be in the ratio of 1 to $1 - r$.

The reflecting powers of a number of diffusing substances have been recently tested by the writer, with results shown in the following table:—

Table I.—*Reflecting Powers.*

	Per cent.		Per cent.
White blotting paper	82	Deep chocolate-coloured paper	4
White cartridge paper	80	Plane deal (clean)	40 to 50
Tracing cloth	35	„ (dirty)	20
Tracing paper	22	Yellow cardboard	30
Ordinary foolscap	70	Parchment (one thickness)	22
Newspapers	50 to 70	„ (two thicknesses)	35
Tissue paper (one thickness)	40	Yellow painted wall (dirty)	20
„ „ (two thicknesses)	55	„ „ „ (clean)	40
Yellow wall paper	40	Black cloth	1·2
Blue paper	25	Black velvet	0·4
Dark brown paper	13		

It thus appears that even a dull-looking wall will reflect as much as 20 per cent. of the light incident upon it. A wall of ordinary tint reflects from 40 to 50 per cent., while a good white surface reflects over 80 per cent. A clean whitewashed ceiling reflects as much light as an ordinary mirror, for although extremely good mirrors may be obtained which will reflect as much as 90 per cent. of the light incident upon them, measurements made with common mirrors do not show a greater reflecting power than 82 per cent.

A room with its surfaces well whitewashed thus needs only one-fifth of the candle-power to produce any given amount of illumination, that it would need if its walls, ceiling, &c., were

Hosted by Google

all painted black. The reflecting power of the walls of a room is an important matter to bear in mind when judging the number of lamps needed to light it properly. Mr. Preece has given a useful rule by means of which an approximate estimate can at once be obtained of the number of arc or glow lamps needed in any given case. This rule is as follows: If arc lamps are to be used for halls, for large buildings, exhibitions, or railway stations, the lamps should be so arranged so that they shed uniformly over the surface to be illuminated the amount of light that corresponds with an expenditure of power in the arcs of one half a watt per square foot of the area to be lighted. For private house lighting, on the other hand, the number of glow lamps should be so chosen that the power they absorb is one watt for every square foot of surface on the floor space. By fixing, 8ft. above the surface, a 16 candle lamp absorbing 64 watts, this will illuminate 64 square feet; so that according to Mr. Preece's rule the area in square feet of the floor divided by 64 gives at once the number of 16 candle lamps, fixed 8ft. high, which will be needed to properly light the room. But it is evident from what has been stated above that a hard and fast rule of this kind can only apply to a room whose walls are of average reflecting power, and that in order to get satisfactory lighting it is necessary to take into consideration the optical character of the walls and furniture within the room. In this connection it may be interesting to reproduce some remarks of Mr. Kapp made some months ago at the Institution of Civil Engineers.* He there stated that "he made a practice of putting in wires suitable for larger lamps, if doubt existed as to the effect of wall decorations. A year ago he had to advise the owner of a large country house with regard to lighting. There were two rooms, each about 100ft. long by 30ft. wide. One room was a museum, used as a ballroom, filled with cases containing specimens of birds, and painted white inside. The other was a picture gallery, wainscoted high up with dark oak. The museum took $\frac{3}{4}$ watt per square foot, and it was then brilliantly lighted. The other room, with the old wainscot, required more than 2 watts per square foot."

This is a somewhat exceptional case; but it is taken from actual experience, and shows that one room may take three times as many lamps to light it to the same extent as another room of the same size. A little consideration will, however, be sufficient to show that in many existing cases the amount of light in a room could be doubled by simply removing the wall-paper and substituting another of a lighter tint. To double the number of lights in the room would not only be much more costly, but would actually in many cases not be so effective as this simple process.

In order to establish this, it is first of all necessary to find out the average reflecting power of the surface of a room, when the walls, ceiling, and floor have, as is usually the case, very different diffusive powers. This average value may be obtained by multiplying the area of every surface by the reflecting power of that surface, adding the products, and dividing the sum so obtained by the sum of the areas of the surfaces.† Thus, if A_1, A_2, A_3, be respectively the areas of the ceiling, walls, and floor of a room, and if the reflecting powers of these areas be respectively r_1, r_2, and r_3, the average reflecting power r may be taken as

$$r = \frac{A_1 r_1 + A_2 r_2 + A_3 r_3}{A_1 + A_2 + A_3}.$$

As an example, suppose the room is approximately cubical, so that A_2, the area of the walls, is four times as large as either A_1 or A_3. In the first instance assume that the tint of the walls and ceiling is dull. We may then take the reflecting power r_1 of the ceiling as 40 per cent., that of the walls, r_2, as 20 per cent., and that of the floor, r_3, also as 20 per cent. We then find that the average reflecting power r is 23·3 per cent., and the illumination produced will be proportional to

$$\frac{1}{1-r} = \frac{1}{1-\cdot233} = 1\cdot30,$$

or 1·3 times what the illumination would be if the surfaces of the room were black. If now the ceiling be whitewashed, so as to reflect 80 per cent., we get for r the value 30 per cent., and the illumination is increased in the ratio of 1·3 to 1·46. If, however, the walls be now covered with a light-tinted paper, reflecting 75 per cent. of the light, the average reflecting power r is

$$r = \frac{80 + 4 \times 75 + 20}{1 + 4 + 1} = 66\cdot7 \text{ per cent.},$$

and the illumination is now represented by the number 3·00, or more than double what it was before the change in the wall paper. Probably an average case for rooms is for the ceiling to reflect 80 per cent., the walls 50 per cent., and the floor 20 per cent. The average reflecting power then comes out to be 50 per cent., and the illumination is doubled by the reflections occurring within the room.

When the surfaces of a room are coloured, the illumination caused by the light is not only increased, but is altered in character by reflective action. Suppose the room has its walls covered with red paper, the average reflecting power of which for ordinary light is 40 per cent. In such a case it may happen that the amount of red light in the room is increased five times by the action of the walls. For, although the average reflecting power of the paper is only 40 per cent., the paper may reflect quite 80 per cent. of the red light falling upon it, absorbing all except, say, 10 per cent. of other kinds of light. In such a case the red light will be increased fivefold, while light of other hues will not be altered to any perceptible extent. The light within a room thus exhibits a strong tendency to become coloured to the same extent as the surfaces of the room.

The reflecting power of a white surface has often been taken advantage of in cases in which a uniformly diffused light is desirable. Thus in factories, in which rather delicate mechanical work is carried out, a suitable light has been obtained by reflecting light from well-whitewashed surfaces by placing arc lights within big funnel-shaped covers arranged so as to throw the light up to a ceiling, and from thence into the room. An arrangement of a somewhat similar kind has been used with excellent results in the lighting of large reading rooms. It appears from the fact that good white surfaces reflect fully 80 per cent. of the light incident upon them, that such arrangements as just indicated not only result in the production of a pleasant diffused light, but are also highly efficient. For instance, if a naked arc light be surrounded by an opal globe there is, as a rule, quite as much light absorbed by the globe as in the double reflection from two whitewashed surfaces, supposing the arc is placed within some such arrangement as that mentioned above.

(To be continued.)

* See the discussion on Mr. Trotter's Paper on "The Distribution and Measurement of Illumination." Proc. Inst. Civil Engineers, May, 1892.

† For the proof of this as well as of other formulæ given later on in this article the reader is referred to a Paper on "The Diffusion of Light," by the present writer, appearing in the *Phil. Magazine* for February, 1893.

MAGNETOMETRIC METHOD OF MEASURING LOSSES IN IRON UNDER ALTERNATING MAGNETIC FORCES.

BY J. E. MOORE.

In the *Electrical World* of June 3, 1892, there appeared a short article on the "Losses in Iron under Alternating Magnetic Forces." The experimental work in the article referred to was performed by a method suggested by Dr. Louis Duncan, which might be called the "Dynamometer Method." Shortly after the publication of this article, the writer had occasion to perform a series of experiments by a modification of this method, which up to that time, it is believed, had never been used. The fundamental object in these experiments was to establish a simple and accurate way of obtaining the iron loss for the predetermination of the efficiency of transformers. In previous methods the measurement of the induction **B** and the intensity of magnetisation **I** had been accomplished by measuring an induced E.M.F. To pass from the instantaneous values of E.M.F. to the corresponding absolute values of **B** or **I** is a laborious process, not to mention the inaccuracies that are apt to be involved.

Hosted by Google

In order to measure all quantities directly, the sample of transformer iron is procured in the form of long strips, or wires, which are built up so as to make long rods. These are supplied with magnetising coils as if they were to be used for ballistic or magnetometer experiments. An alternating current of the same periodicity as that for which the transformer is to be used is passed through the magnetising coil. It produces in the sample waves of magnetism of the same periodic time as the current. Instantaneous values of the magnetising current can be measured by the method suggested by Dr. Duncan. The corresponding values of magnetisation can be measured by suspending a small helix of insulated wire near one of the poles of the long rod. By passing an instan-

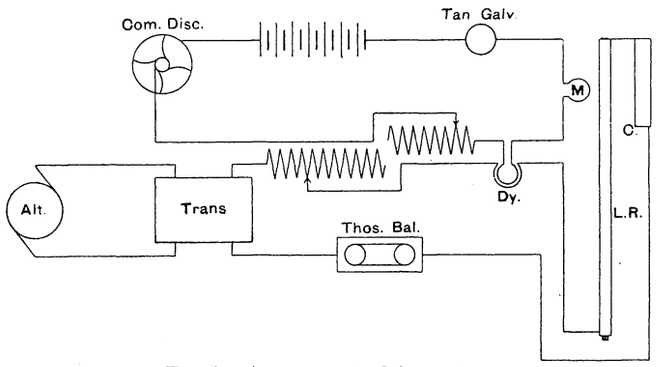

FIG. 1.—Arrangement of Apparatus.

taneous current through the helix at a definite point in each recurring cycle of magnetism in the long rod, the helix is made for a very short time a magnet, the strength of which is proportional to the number of turns of wire on the helix and to the current passing. It is readily seen that a deflection will result; and its amount will be proportional to the product of the strengths of magnetism developed in the long rod and the suspended helix during the short time the current is flowing through the helix. By making the instantaneous current to pass at different points in the wave of magnetism, different magnetometic deflections will be obtained at each point, and by keeping the mean strength of

the instantaneous current constant, the deflections of the helix will be proportional to the strength of magnetism in the long rod at the point in the wave of magnetism at which the instantaneous current passed. By this modification both quantities for obtaining the hysteresis loss may be read off directly. Since this method differs from the dynamometer method only in the use of the magnetometer, it will suffice here to describe this piece of apparatus alone.

The magnetometer M (Fig. 1) was made of a helix of insulated wire 2·5 centimetres in length, and 1·5 centimetres in diameter, suspended bifilarly within a stout wooden upright, which was made fast to a suitable base. A mirror was attached to the helix, which allowed its deflection to be read by a telescope and scale. The oscillations were damped by suspending from the under side of the helix a small copper plate, which was immersed in sulphuric acid. The length of the helix was carefully adjusted to be in the magnetic meridian. This could be easily tested by passing the instantaneous current through the helix; if no deflection occurred it was known to be in the proper position. The magnetising coil of the long rod LR was placed vertically, and before inserting the specimen, or beginning an experiment, a balancing coil C was so adjusted that no deflection of the magnetometer helix was caused when the full magnetising current was passing. At the end of the experiment the balancing coil served as a means of calibrating the magnetometer by passing a known continuous current through it.

FIG. 3.—Experiment on Long Rod of Wires $\sqrt{C^2} = 2 \cdot 3025$ amp.

In Figs. 2 and 3 are shown results taken by this method from a rod 122·8 centimetres long made up of 40 No. 16 iron wires. The lag between the magnetising force and the resultant magnetisation, as caused by eddy currents is very plainly shown. In the results presented a correction is introduced by resolving the magnetising force in the direction of the resultant magnetisation, and subtracting from it the component of the eddy currents resolved in the same way. It is to be noticed that the corrected losses agree very closely with "static" hysteresis losses at corresponding magnetisations obtained by either the ballistic or magnetometer methods.

ELECTRICITY FOR CHEMICAL LABORATORIES.

The growing use of electricity in chemical operations, whether manufacturing, experimental, or purely analytical, has made it necessary to have some source of current in every laboratory devoted to technical research and to many others concerned with more conventional chemical operations. In a town where there is a regular supply, current can, of course, be laid on much as if it were to be used for lighting, although the facts that the normal pressure at which it is delivered, and that many electric lighting companies supply alternating currents, make the adoption of some special means for suiting the users' needs, occasionally necessary. Apart from this, however, there are many laboratories where no supply from without can be obtained, and the problem then arises how to find an efficient substitute which shall be neither unduly costly nor need excessive attention on the part of the user. Where power in any form is available it seems tolerably simple to put down a small dynamo; but this necessitates the use of accumulators, as it is but rarely that the ease and certainty with which any

Hosted by Google

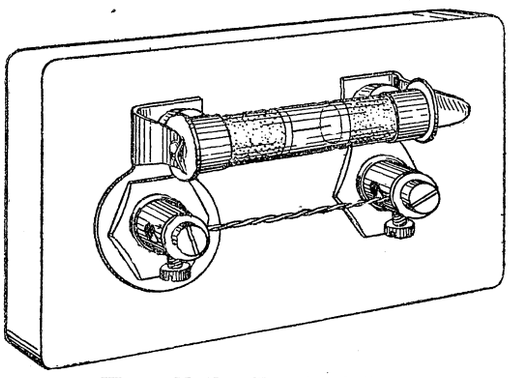
required pressure and output can be obtained by their means, can be dispensed with by a chemist whose needs may include the deposition of copper or nickel and the use of a miniature electric furnace on one and the same day. Primary batteries are not to be thought of, as they are either incurably messy and troublesome or they require such an enormous number of cells for a moderate output that their first cost and subsequent maintenance become serious items of expense. The thermo-electric battery has deservedly won a bad name for itself, because it has claimed to do too much, but used for its proper purpose, namely, to supply a small current for an indefinite time without attention, it has much to recommend it. By using it in conjunction with storage cells a fairly simple and practical generator can be provided which will satisfy most of the requirements of a modern chemical laboratory without adding appreciably to the work of the place, which is often fully as heavy as can be efficiently performed by its occupants. An arrangement of the kind has stood the test of experience in the laboratory at Freiburg, and is described in a recent number of the *Chemiker Zeitung* by Dr. Karl Elbs.

The following are the chief features of the plant. There are eight small accumulators, with a capacity of eight ampere hours apiece, and a Gülcher thermo-electric battery of 66 elements. The accumulators are divided into two groups of four, and can be coupled in series or parallel, as may be required. A resistance box with resistances of 2 ohms down to 0·1 ohm and a Gaugain galvanometer are provided, and a commutator by means of which the direction of the current can be reversed through the galvanometer without affecting the main circuit is also fitted. The thermo-electric battery is heated by gas, and needs no governor or thermostat, as the variation produced by fluctuation of the gas pressure is not large. Its mean voltage is 4·1, with an internal resistance of 0·68 ohm. When the gas pressure varies from 20 to 35 mm., these values vary from 3·8 and 0 65 to 4·3 and 0 75 respectively. Under ordinary circumstances, the current is practically constant, and for one hour the consumption of gas is only 170 to 180 litres, costing at Freiburg three pfennige. To get as good an output with primary batteries, either two large Bunsens in series, or 60 Meidingers coupled in four groups of 15 cells in parallel, would be requisite. The accumulators are of the German Post Office pattern, each cell containing one positive and two negative plates attached to a porcelain cover, and immersed in sulphuric acid of sp. gr. 1·15 contained in rectangular glass cells of a capacity of about a litre. Each cell gives a mean voltage of 2·05, the internal resistance is 0·05 ohm, and the maximum output 8 ampere hours, as stated above, with a maximum current of 3 amperes. The thermo-electric battery and the accumulators are generally used together, and by shifting the connections of the two groups of cells and of the members of those groups, arrangements for work of the most varied character can be made, care being, of course, taken that the current delivered by any one cell does not exceed 3 amperes. The accumulators are connected in parallel for charging, and each group can be charged separately or the two groups in parallel as may be more convenient. The complete charging of the accumulators can be effected in 30 hours, but the natural pauses of work general suffice to allow the thermo-electric battery to keep them fully charged, so that stoppage for the express purpose of recharging is rarely necessary. If the accumulators are kept clean they will retain their charge almost undiminished for months. The experience gained at Freiburg shows that no appreciable injury results from keeping the whole apparatus in the laboratory itself, exposed to what fumes may arise, while if a specially trying atmosphere is expected, the simple precaution of covering the whole with a cloth is a sufficient safeguard.

As far as can be seen the plan that has been described is a convenient one, and likely to be appreciated by all those who have had to put up with the malodorous nitric acid cell as a source of current. In these days when a big town has current supplied from central stations almost as a matter of course, one is apt to forget that all places are not equally favoured, and that the scientific or technical worker isolated by the exigencies of his position is a man and a brother after all, and deserves occasional consideration.

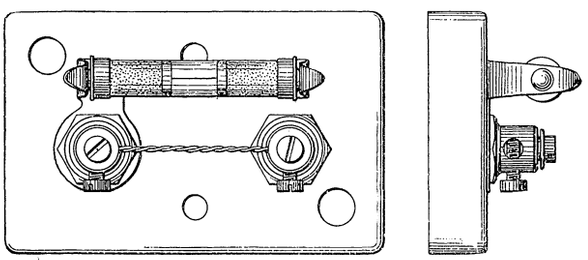
THE WATSON-MORDEY SHORT-BREAK FUSE.

The careful work that has been done on the practical and theoretical determination of the melting point of fuses is of little or no avail in the design of cut-outs for high voltages. When such a fuse "goes," the wire is wholly or partially volatilised, and an arc is easily formed across the metallic vapour. A three-foot break is not sufficient to prevent the formation of such an arc, and mechanical shutters to cut it off have been tried, but have given place to large porcelain blocks which enclose the long fuse wire, and appear to absorb the heat so quickly that an arc cannot be maintained. While convenient enough in an engine-room or transformer station, space cannot be found for such an arrangement in a boxed-in transformer.



Watson-Mordey Short-break Fuse.

At the last reception evening of the Institution of Civil Engineers, among various objects of interest exhibited by the Brush Electrical Engineering Company, we noticed some new cut-outs which have been designed for high voltages, but which are of very compact design, and well suited for placing inside the cases of even small transformers. The device consists of two fuses, one a simple fuse arranged to melt at a certain current, and the other a fine wire placed in shunt. The fine wire fuses



Front and Side Elevations of Watson-Mordey Short-break Fuse.

immediately after the main wire, but the arc is at once "killed" by the action of a non-conducting powder packed in a glass tube. The action is probably mechanical, splitting up the arc as the London police disperse an unauthorised street procession. Mr. Mordey informs us that he has never succeeded in forcing an arc through one of these tubes, and that he would be prepared to make them only one inch in length if worth while. The action of the shunt in preventing arcing at the main fuse has been severely tested. The shunting was proposed by Mr. Mordey in the discussion on Mr. Cockburn's paper in 1888. It is hardly necessary to add that the base of these cut-outs is of glazed earthenware, and that no metal parts are visible at the back.

Electric Lighting in Parliament.—The electric light has at last found its way into the House of Lords. At a quarter to 3 o'clock on Tuesday afternoon last the House was, for the first time in a public sitting, lighted by electricity. The ten clusters of Swan-Edison lamps suspended from the ceiling are said to be a very appreciable improvement upon the gas sunlights which they have superseded.

THE SIMPLIFICATION OF THE QUADRUPLEX, AND THE IMPORTANCE OF ITS ACHIEVEMENT.*

BY D. H. KEELEY.

If there is any one thing more than another in the domain of practical telegraphy that hangs on the consideration of fine points, it is the successful operation of a quadruplex system, and to those who have had opportunity for inquiring into the philosophy of the thing, this fact is more than patent, inasmuch as it is found that a very serious difficulty exists where at the outset none whatever is apprehended. As a matter of fact, when the quadruplex was a novelty and not yet in extensive use, the text books were silent on the one vital, but seemingly unimportant, point to which the delay in developing the system was referable, and it was some time before the really difficult part of the problem was appreciated and understood by any excepting those immediately concerned in its conception. However, that time is past, and the student of to-day in consulting his text book will find the whole anatomy of the quadruplex laid bare, and the devices introduced to obviate the difficulty that is due to an *inherent d fect* are taken into account as an essential part of the whole. That, at any rate, is the point of view from which this paper is written; and its object is to show, in the first place, that in the established system of quadruplex telegraphy there is an inherent defect whose obviation has encumbered the fundamental principle with complex apparatus—thereby, from a theoretical standpoint at least, demonstrating its inadequacy; and, in the second place, to show how, by building upon a different but equally simple principle, the same practical results can be secured with much less machinery.

With this end in view, a little consideration can now be given to a comparison of the different principles involved, and, incidentally, the whereabouts and character of the inherent defect to which allusion has been made will be perceived, and the method proposed for its elimination understood.

For convenience of elucidation it will be well to start with the conception that a quadruplex is a combination of two duplexes. A duplex is a system in which the recorder at each end of the line is so arranged as to be unaffected by currents outgoing, while free to respond to currents incoming. In the quadruplex, therefore, the distant recorders respond to the home keys or transmitters, and the home recorders respond to the manipulation of the distant transmitters; the result of which is that a single conductor is made to afford four distinctive circuits. These circuits, however, are not precisely similar, because the constitution of a quadruplex is such that the duplex element cannot be lost sight of, and a system of this kind is, therefore, necessarily always regarded as having *two sides;* the apparatus on one side (one of the two duplexes) being operated by currents differing in polarity or in degree from those operating on the other side. The trouble has been to obviate not only the liability but the *possibility* of an interference of one side with the other.

The several methods of quadruplex telegraphy that have been invented are comprised in two general classes. (1) The *polar systems*, or those in which the receivers on the one side are actuated by increase and decrease of a normal current, and on the other side by reversals of that current, and (2) the *straight current systems*, or those in which the receivers are actuated by three different strengths of current of a given and unchanging polarity.

We can best consider them separately under distinctive headings, and assume a practicable type as embracing the whole in each instance.

The Polar Quadruplex.

It is the polar quadruplex that has found favour in practice; but it presents several undesirable features, and, excepting where dynamic currents are available, is expensive to maintain, in consequence of large batteries being required for its exclusive use.

According to this method, the signalling battery is arranged in two sections. One of the transmitters operates to put one or both of the sections to line; and the other transmitter operates to reverse the direction of the current. The receiving apparatus consists of polarised and neutral electro-magnets. The armature lever of the polarised instrument is normally held against its limiting stop by the − current of the smaller section of the battery, that traverses the line when both of the transmitting keys are at rest (upraised), and it remains in the same position when the key that puts the second section of the battery in circuit, is depressed; but it passes freely over to its front stop or signalling contact when the + current, from one or both sections of the battery, traverse the circuit: hence the polarised instrument responds to the manipulation of the reversing key. The armature of the neutral instrument is responsive to both − and + currents, but it is held back by a retractile spring exerting a greater force than the magnetic attraction due to the current from the smaller section of the battery. This latter can, therefore, be reversed repeatedly and continuously, thereby producing signals on the polarised receiver, without in any way affecting the neutral instrument. Whenever the increment key is depressed, however, the current from both sections of the battery traverses the circuit, the retractile force is insufficient to withstand the magnetic attraction imparted to the neutral receiver, and its armature passes over to its front stop or signalling contact; the neutral relay is thus responsive to the manipulation of the increment key.

So far the action appears to be smooth and satisfactory, and one might think he could go to work and set up his quadruplex; but he will discover, as did many an early investigator, that his knowledge is as yet incomplete. It will be found that while no effect is produced on the neutral relay by the changes of polarity of the smaller section of the battery, there is a marked interference when the current of both sections together is traversing the circuit. When the increment key is depressed the neutral receiver responds; if now, the reversing key is depressed, a short false signal will be produced on the neutral receiver. The reversal of the battery by the reversing key momentarily withdraws the current from the circuit, and in that brief interval the magnetic attraction of the neutral receiver drops sufficiently to allow its armature to fall back from its signalling contact.

Here, then, we have the inherent defect of the system clearly defined. It resides in this lack of continuity of current.

Divers devices—perhaps multitudinous is a better word to describe their number—have been worked out with a view to obviating this ill effect of the current reversals. Out of them all, the clever arrangements due to the ingenuity of Messrs. Gerritt Smith and F. L. Jones have been sifted and adopted in the standard quadruplex of the telegraph companies. There is not much to choose between these two devices; they are distinctive types, and have gone a long way to make the quadruplex what it is. Smith puts an extra coil on the neutral receiver core and connects it in circuit with a condenser shunting a considerable resistance. The current from both sections of the signalling battery charges the condenser, and the instant the current is withdrawn the condenser discharges through the shunted resistance and the extra coil on the neutral receiver, the magnetic attraction of which latter is thereby maintained. Jones substitutes an induction coal for the condenser; the secondary wire is in circuit with the extra coil on the receiver, and the primary is traversed by the current from both sections of the signalling battery; the instant the current is interrupted an induced current traverses the extra coil, and, as in the other case, retains the armature attracted.

Either of these devices necessitates the use of heavier currents than would be required for the mere production of signals on the receivers, because the condenser discharge and the induced wave have to impart nearly the same degree of magnetism as the transmitted current, so it is found that the coils traversed by the transmittted current in the standard quadruplex of to-day are not designed to produce a maximum magnetic effect, whereas the coils traversed by the seconday currents are designed to that end and wound to suit the high potential of the condenser and induction coil discharges.

It is seen now that the feature of heavy currents has been dragged into and made a necessary part of the standard quadruplex, in consequence of a defect that seemingly could not in any other way be surmounted.

Let us see whether this feature of heavy currents is attended with any considerable drawback.

In consequence of electricity being as a general thing now so plentiful and cheap, it might at first sight be considered immaterial, from an economical standpoint, whether heavy or light currents were used in the operation of the quadruplex; but we have to bear in mind that only a small percentage of the telegraph wires of this Continent are supplied by dynamos, and that, as regards the vast majority of cases, the customary galvanic battery is in use the world over, and its cost is just as great now as it was fifteen or twenty years ago. This fact, dealing with the quadruplex alone, is in itself worth looking at; but when we go further and consider the circumstance that in the course of operation of a polar quadruplex, the positions of the transmitting keys are at times such as to throw the entire current + from one end and − from the other into the line, whence it follows that the line becomes inordinately charged, and by induction would interfere with every other circuit running parallel with it were they not also supplied with otherwise unnecessarily large currents in order to obviate the ill effects occasioned in them—we can appreciate the very great importance of this question.

A few years ago, before the days of the quadruplex, our telegraph circuits were equipped with receivers designed to afford a maximum of magnetic attraction, and the necessity for anything like large currents did not exist. The ordinary run of the old relays measured in the neighbourhood of 300 ohms, and we could get good work out of them over long distances. To-day the ordinary run measures 150 ohms, and without going into calculations

* Paper read before the Canadian Society of Civil Engineers.

Hosted by Google

we can see that on a given line the latter instrument will be less efficient than the former, and to make it answer our purpose an increased current must be supplied. So we have perforce reduced the sensitiveness of our apparatus and increased our currents; and this it appears is the only way we could keep pace with the quadruplex, for had the more sensitive instruments with comparatively weak currents been retained, the induction from the quadruplex circuits would have rendered the ordinary single circuits well nigh inoperative.

We see in all this, then, that the advances made in telegraphy, while admittedly very great from a practical standpoint, have been at the sacrifice of an economic and a scientific principle.

Is it now too late to rectify this error and to return to the old and economical practice that was departed from? Perhaps if an improvement in quadruplex apparatus, recently devised with a view to dispensing with the necessity of heavy currents, had been hit upon some twelve or fifteen years ago, this regrettable departure from the old practice might have been averted; and even now it might suggest the practicability of going back to first principles, if the advantages to be gained thereby were considered of sufficient importance to warrant the reversion.

The improvement refered to is in connection with, and might now be taken into consideration under the head of

The Straight Current Quadruplex.

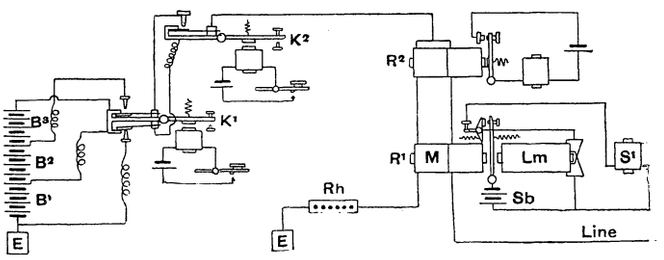
In this system the signals are produced, as has already been stated, by three different strengths of current of a given polarity. This method of transmission was for a long time the favourite hunting ground of inventors seeking a solution of the problem of sextuplex telegraphy. It appeared to be an easy matter to form a quadruplex on this plan, and add thereto the reversing key of the polar system and thus obtain as many as six circuits in a single conductor. It, however, came about in the long run that the formation of the quadruplex itself, according to this method, was extremely problematical. As a matter of fact, there never was a straight current quadruplex in practical operation. The difficulties that were presented in the way of its successful adoption have, however, been investigated in many quarters, and the invention, as a whole, has in the course of time been improved to an extent that warrants its now being characterised *the simplified and perfected system.*

That this simplified quadruplex is fairly calculated to fill the bill already outlined for the practicable operation of the general telegraphs on currents of much less power than are at present employed, will be recognised in view of the fact that the straight current quadruplex, as a system, presents none of the objectionable features of the polar system already pointed out. There are no reversals of the current to occasion disturbance in one of the receivers, so the necessity for extraordinarily large batteries for the operation of devices such as those described is done away with; and there is no need to charge the line beyond the voltage of the maximum current emanating from one end alone, because a system of this description is operative with either like or unlike poles to line, so there are no ill effects due to induction communicated to circuits adjacent to the line upon which this quadruplex may be in operation. The importance and value of the invention need not, perhaps, in view of these facts be further emphasised.

The straight current quadruplex in its simplest and perfected form is shown in the accompanying diagram. It will be noticed that the signalling battery is in one unbroken series, with its −pole to earth. The terminal and two top wires are connected with the transmitters, which operate to put the main line in connection with the battery at some one of the three points tapped according to the position of the transmitter levers, and in this way the requisite three strengths of current are presentable for the transmission of signals. The battery being in one unbroken series with one pole constantly to earth, is rendered available for the supply of current to other wires or circuits independent of the quadruplex; just as in the case where several Morse circuits are supplied from a single battery common to them all in one of the regular main offices. This is a feature of great advantage, as it obviates the necessity for separate and exclusive batteries for the operation of the quadruplex circuits. This arrangement of the battery and transmitters was supposed to have originated quite recently, along with a further improvement of the writer's to be described further on. But an examination of the files of the United States Patent Office disclosed the fact that its invention was anticipated, as far back as January, 1877, by Benjamin Thompson of Toledo, to whom it was patented (No. 195,055) in September of that year; and it is perhaps due to the unfortunate circumstance of its being covered in conjunction with an unwieldly and inadequate mass of receiving apparatus, that it never worked its way forward to the recognition that its merit deserves. As will be seen by an examination of the diagram, the transmitters are so connected that when both of the levers are upraised the line is to earth; when K^1 alone is depressed, the line connects with B^1; when K^2 alone is depressed, the line connects with B^3, and when both K^1 and K^2 are depressed, the line connects with B^2. It follows, therefore, that K^1 sends the minimum current to line; K^2 sends the maximum current to line; and when both keys together are in action, an intermediate strength of current goes to line. At the distant end there are two receivers. One of them is an ordinary duplex relay, R^2, connected in the usual way; a retractile spring holds its armature with a force superior to the magnetic effect of the minimum current, but it is responsive to the intermediate and maximum currents; R^2, therefore, freely and readily responds to the manipulation of the transmitter K^2. The other receiver comprises the distinctly unique feature that has raised the straight current quadruplex to its present perfection. Its contrivance is such that the sounder or recording instrument operating in its local circuit responds promptly and accurately to the manipulation of K^1, under the action of the minimum and intermediate currents, while the maximum current produces upon it absolutely no effect whatever. In this arrangement the sounder is operated directly by the armature lever contacts, and there is consequently no enfeeblement of the signals and no uncertainty whatever about its action. In consequence, the transmissions on both sides are equally rapid and reliable. For the information of those interested in the solution of the problem involved, a detailed explanation of the receiver R^1 is given in the accompanying note.

A test which the writer was enabled to make, in conjunction with Mr. H. Bott of Ottawa, on a line between this place and Toronto, nearly 300 miles long, showed that the apparatus would respond properly to currents (=·038 amp. max.) derived from batteries of 150 cells at each end of the line. On the selfsame line wire the standard polar quadruplex is regularly operated with currents (=·070 amp.) derived from batteries of 275 cells at each end of the line; which, under certain positions of the transmitting keys, produces in the circuit a current of (·070 × 2 =) ·140 amp. max. from the combination of the (275 × 2 =) 550 cells.

The comparison speaks for itself.



We have now arrived at the conclusion of this Paper. Its purpose has been to show that the practice of telegraphy to-day, despite the many advances that have been made in the service in one way and another, is not so scientific as we find it to have been so long as twenty years ago. An endeavour has been made to show that the development of the polar quadruplex, now so extensively used, has occasioned this departure from first principles, and how the now perfected straight current quadruplex would admit of a return thereto. And the question submitted for consideration is, Would it be worth while now to return to the original practice and continue in that good old way?

Note.

In the straight current quadruplex the receiver on one side responds to the stronger currents, and the receiver on the other side responds to the weaker currents. It is obviously an easy matter to prevent the former being interfered with by the currents intended for the latter side, as it is only a matter of adjustment of the retractile force on the armature lever. On the other hand, it is equally obvious that an electro-magnet cannot be constructed to respond to weak currents and at the same time be unaffected by strong ones. As, however, the signals are, in practice, always taken from a second instrument, operating on a local circuit of the receiver or relay, it is possible to so arrange the intervening mechanism that the local circuit shall be closed only when the currents designed therefor are traversing the magnet coils. In the construction of the instrument, therefore, a supplementary lever is hung in such a way as to hold the armature lever in an intermediate position, between its limiting stops, when attracted by the weaker currents. A strong current will attract the armature with sufficient force to carry it beyond the intermediate position, and when there is no current the armature lever falls back to its rear limiting stop. It then becomes only necessary to connect the local circuit in such a way that it shall be closed in the intermediate position of the lever, and open when the lever is in either of its extreme positions, in order to meet the requirements of the case. That, at least, was the assumption; but the idea proved impracticable, in consequence of a brief con-

Hosted by Google

tact, completing the sounder circuit, that was found to obtain in the passage of the armature lever between its extreme limiting stops every time the strong current was applied or withdrawn. This difficulty has never been successfully dealt with until now. In the receiver R^1 an auxiliary electro-magnet, Lm, wound to produce a considerable counter E.M.F., is placed directly behind the relay armature, so as to act thereupon in opposition to the main circuit coils m. In the normal condition, with no current traversing m, the armature lever is held against its back stop by a light retractile spring in the usual way. When a weak current, say the minimum, traverses m, the armature lever is attracted to the intermediate position; this closes the circuits of Lm and S^1; the retractile power (that is, what the magnetic attraction in this case becomes) of Lm is delayed by its own counter E. M. F. until the attraction of m has grown sufficient to retain the armature in the position to which it was drawn, so the closed circuit of S^1 remains undisturbed. The same action attends the intermediate current; so S^1 responds to the minimum and intermediate currents. When the maximum current traverses m, the armature lever is carried from its intermediate position, and S^1 opens, but the circuit through Lm remains uninterrupted. If the current again decreases, the lever returns to its intermediate position, and S^1 closes; but if the maximum current is entirely withdrawn, the armature lever will, in consequence of the steady pull exerted on it by Lm be drawn sharply back to its rear limiting stop. And if, when the armature is resting in the latter position, the maximum current is applied to m, the armature lever will pass directly over to the front limiting stop, in consequence of the counter E M. F. of Lm robbing it of any retractile power during its passage across the contacts in the intermediate position. There is, therefore, no hindrance to the forward movement of the armature, and there is an acceleration of its movement rearward; hence the maximum current can be applied and withdrawn at pleasure, without in any way affecting the local circuit by which the sounder S^1 is operated.

EXPERIMENTAL RUNS WITH A BUDAPEST ELECTRIC CAR.*

One of the cases in which electric traction is applicable, while horse-power is out of the question, is that in which steep inclines have to be surmounted; and another case is that in which high speeds are required. Owing to the comparatively great weight of the electric car and its machinery the adhesion of the wheels to the rails is greater and should enable considerable inclines to be easily surmounted. In order to experiment on this subject a trial line was constructed, with inclines of 1 in 10 and 1 in 19, on which trial runs were made, which proved that even inclines of 1 in 10·42 can be easily surmounted, so that in very steep lines the difficulty of the brake would be greater than that of climbing the incline. The results of the tests are fully given in the table below:—

	No. of Experiment.			
	1	2	3	4
Weight of car.....(tons)	4·13	4·13	4·13	4·13
Load .....(tons)	2·40	2·40	0·37	0·37
Total weight of car...(tons)	6·53	6·53	4·50	4·50
No. of driven axles	2	1	2	2
Length of trip in yards ...	34·0	34·0	32·8	32·8
Incline	level	level	1 in 18·95	1 in 10·42
Time of trip in seconds ...	51	50	8	14
Speed, miles an hour	13·7	13·95	8·37	4·77
Revolutions per minute of motor	549	560	337	192
Volts	282·5	285	266	260
Amperes	26·0	24·5	54·0	68·0
Watts	7,345	6,982	14,364	17,680

Tractive force, lbs. per ton				
On the horizontal	33·6	33·6	33·6	33·6
On the inclines.....	...	...	118·2	215
Total tractive force lbs.	33·6 × 6·53 = 219·0	219·0	(33·6 + 118·2) × 4·5 = 683·0	(33·6 + 215) × 4·5 = 1120·0
Mechanical horse-power ...	8·14	8·29	15·27	14·30
Efficiency— $\frac{\text{Mech. H.-P.}}{\text{El. H.-P.}} \times 100$	82·57%	88·62%	79·41%	60·37%
Losses by friction of gearing, &c., and conversion of energy	17·43%	11·38%	20·59%	39·63%

* From the *Zeitschrift für Elektrotechnik*.

All experiments were carried out at night, in order that the fluctuations of pressure due to the working of the line might be avoided. The car was always started outside the trial line proper. Every set of observations is the mean of a series. The car with which the experiments were conducted was an ordinary car of the Budapest Electric Tramway Company, with simple chain gearing of 11:31 from the motor to the axle. As the motor was not sufficiently strong to carry the fully loaded car up the steep inclines, the experiments on these parts of the road were done with a smaller load. The efficiency dropped while ascending the hill owing to the speed of the motor being so low.

These experiments go to show that the electric car is capable of working on lines where the steepness of the inclines would render horse traction out of the question.

THE REFRACTIVE INDEX OF ELECTRIC WAVES IN ALCOHOL.*

BY H. O. G. ELLINGER.

The refractive index was determined for alcohol of 96 per cent. strength. A preliminary investigation showed that alcohol was transparent to the waves. The alcohol was then placed in a prism-shaped vessel of wood, 1 metre high, 1·15 metre long, and having an angle of 8° 16′, holding 90 litres. In order to show the Hertz spark in the secondary reflector, the primary reflectors had to make an angle of 33deg. with one another. This gives an index of refraction for alcohol of about 4·9, a value which accords very fairly well with theory, as the specific inductive capacity (from an average of several observations) has a value which differs but little from $(4·9)^2$.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY) FRIDAY, February 3rd.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. "Description of the Pumping Engines and Water-Softening Machinery at the Southampton Water Works," by William Matthews.

SOCIETY OF ARTS.

8 p.m. Howard Lecture (4): "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Theory and Practice in Electrical Science" (with experimental illustrations), by Alexander Siemens, M.Inst.C.E.

MONDAY, February 6th.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at Westminster Town Hall Presidential Address, by W. A. M. Valon.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture (2): "The Practical Measurement of Alternating Electrical Currents," by Dr. J. A. Fleming, F.R.S.

TUESDAY, February 7th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be further discussed: (1) "Smelting Processes for the Extraction of Silver and Gold from their Ores," by Henry F. Collins, A.R.S.M. (2) "The Erection of Silver-Lead Smelting Works in Mexico," by James W. Malcolmson, Wh.Cc. At this meeting the monthly ballot for members will be taken.

WEDNESDAY, February 8th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Some points in the Chemical Technology of Oil Boiling, with an account of a New Process for preparing Drying Oils for Decorators' and Artists' use." By Prof. W. Noel Hartley, F.R.S.

THURSDAY, February 9th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting "Experimental Researches on Alternate Current Transformers." Dr. Fleming's reply to the Discussion. Paper to be read: "Note on Testing Alternators." By W. M. Mordey.

FRIDAY, February 10th.

PHYSICAL SOCIETY.

5 p.m. Annual General Meeting. After which the following Papers will be read: (1) "Recent Determinations of Molecular Refraction and Dispersion," by Dr. J. H. Gladstone, F.R.S.; (2) "The Separation and Striation of Gases," by E. C. C. Baly.

* Abstract from *Wied. Ann.*, No. 1, 1893, p. 108.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price : Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE PRESENT POSITION OF THE ALTERNATING MOTOR PROBLEM.

Of all the problems in electrical engineering which have taxed or are taxing the energies of some of our most fertile inventors and practical engineers, that which seems to be one of the longest in finding an effective solution is the alternating motor problem. It may, indeed, be said that some of those who have worked the hardest in this direction have abandoned the simple alternate-current motor as an impossibility, and this probably was the cause of the intensity of the *drehstrom* fever whilst it lasted. It is interesting to observe, therefore, that although there has been a subsidence of the feeling that the rotary-phase motor was the solution, not only of the alternate-current motor problem, but of all questions in power transmission and distribution, the latest addition to the already long list of single current motors comes from one of the high priests of multiphase currents. In our last issue we gave a description of a motor designed by Mr. C. E. L. BROWN, which, in reality, is not so much a new motor as a conglomeration of old motors, salted with the practical ingenuity which Mr. BROWN has so usefully displayed in this class of machinery. At this time, therefore, when renewed interest centres round the alternating motor, it may be well to consider how far we have got in the ten years, or thereabouts, that have elapsed since a motor capable of working with alternating currents first was wanted.

Hosted by Google

The original idea was that any motor would work with alternating currents if only both field-magnets and armature were laminated; but it was soon found that the output was almost *nil*, and that the current in the armature coils under the brushes, were like short-circuited secondaries on a transformer, and gave rise to considerable heating and sparking. Then came Dr. HOPKINSON with his historical lecture at the Institution of Civil Engineers in 1883, in which he showed that an ordinary alternating dynamo would run as a motor synchronously with the generating dynamo. After this ELIHU THOMSON struck a new vein in a motor, in which the alternations of magnetism in the magnetic circuit, set up by a primary or magnetising current, gave rise to currents in the rotating armature, which, normally symmetrical to the magnetic axis, were placed in an unsymmetrical position by various devices, so as to produce a rotary effort. Now, as an evolutionary process the TESLA motor and all multiphase motors would follow from this as particular devices for producing an induction current in a rotating coil unsymmetrical to a magnetic axis, and the motor of Mr. BROWN, just referred to, is another particular case of this class of motor. The TESLA motor, which was brought forward in 1887, was an independent creation, and for a time was thought to be *the* solution of the question. Next, after being enveloped in mystery for some months, the GANZ alternating motor was described, and turned out to be a synchronous motor, which, by a commutating device for rectifying the magnetising current of the field magnets, was made self-starting, and was asynchonous within certain limits without losing its rotary effort. Since this time no real novelty of principle in alternating motors has been developed. What has taken place has been to improve, combine, and adapt for specific purposes.

How then, at the present time, does the question of adapting alternating motors for specific purposes stand? There may be said to be two distinct problems: (1) Transmission of power; (2) Distribution of power. For the first, on a large scale, the question of whether the motor will start itself, or must be started by an independent apparatus, such as a group of secondary batteries charged from the exciter, and in turn operating the exciter as a motor, is not of vital importance, and for this class of work the synchronous alternating motor has proved itself very effective, simple, and of high plant efficiency. For this purpose also the three circuit multiphase motor has shown itself admirably adapted. For transmission work motors only need to be able to carry an overload to the extent of, say, 50 per cent. without stopping or appreciably slowing, to effect all that is needed, whilst the absence of commutators, and the possibility of transforming up and down to and from the line makes them applicable to any voltage that insulating materials will stand. The transmission problem, in fact, has met with two very satisfactory solutions.

When, however, we come to distribution of power, we are met with quite another condition of affairs. The requirements are absolutely different. No motor (steam, gas, hydraulic) meets the requirements of power distribution as does the direct current electric motor; if only we could do away with the commutator. This, which in properly attended machinery on a large scale gives with moderate voltage no practical trouble, is the bane of the electric motor. No alternating motor with a commutator can be considered a solution of the problem of power distribution, it is merely a motor which can be applied to an alternate-current supply system. The multiphase motor, of course, gets over the difficulty, but multiphase electric distribution is already seen to be almost too complicated to become the solution of the problem. Hence we are brought back to the single current alternating motor, commutatorless and asynchronous. Does such exist? There is little doubt that the motor described by Mr. BROWN, and illustrated in Figs. 7, 8, 9 of the article in our last issue, is the nearest approach to this ideal so far developed. It is commutatorless, it works normally with a single alternate current, it will start with a torque double of the working torque, by a simple and *commutatorless* arrangement of double winding the speed within certain limits can be varied, and the plant efficiency is high. Whether this solution is a final one remains to be seen, but all indications at present point to the induction motor first invented by ELIHU THOMSON as the motor of the future. What device will be adopted to produce the unsymmetrical position of the active motor coil remains to be seen. The short circuiting devices of ELIHU THOMSON acting by only closing the circuit of an unsymmetrical coil, is only the commutator in probably a worse form. The multiple-phase method producing a magnetic axis unsymmetrical (considering any one coil) with the axis in which the inducing magnetism acts, is complicated. The arrangement of Mr. BROWN depending on the rotation of the coil itself into any unsymmetrical position, after the magnetic induction has acted, is certainly simple, and, at all events, opens up a new branch.

THE CAMBRIDGE UNIVERSITY ENGINEERING LABORATORY.

A general committee, consisting of a remarkable collection of able and distinguished men, has been formed to appeal for financial help in carrying out the equipment of an Engineering Laboratory at Cambridge. It is noteworthy that the preliminary subscription list, as well as the committee list, contain a number of names of non-university men.

Nearly two years ago a Report was communicated to the University of Cambridge on a proposed Engineering Laboratory, and we called attention to it in these columns with nothing but the best wishes. There was then no hint, or none that we detected at the time, of an engineering Tripos, and with a slight reservation on the score of the attempts which are made at certain establishments to turn out ready-made engineers, though indeed this was distinctly discountenanced in the Report, we unhesitatingly welcomed the proposal. A little more than a year later an engineering Tripos was advocated, and this departure we as unhesitatingly deplored; it is as much at variance with the spirit of the older Universities as indeed it is with that of the Laboratory Report. Of the four acknowledged objects of the Laboratory—that it makes the student's knowledge of mechanical principles more real by bringing him into contact with material examples; that it gives him practice in those kinds of experimental work which he may afterwards have to perform in professional life; that it teaches him how investigations are to be conducted, and gives him some experience in this higher work; and, lastly, that it endeavours to contribute to the common store of knowledge by affording opportunities and appliances for original research—the second alone suggests the utilitarian *Brod-Wissenschaft*, and points to the danger, as Lord PLAYFAIR recently put it, of the degeneration of the University into a bread-and-butter institution. The same authority quotes from EPICTETUS that though sheep eat grass, it is not grass, but wool, which grows on their backs; and while it was said at first that neither the workshops nor the laboratory at Cambridge attempted "to supersede the practical training which a pupil must receive in the office of an engineer, or in engineering works," it seems necessary to

Hosted by Google

remind students, at all events, that though engineers must assimilate mechanical science, it is not engineers, but men capable of becoming engineers, that a University laboratory, or even a Tripos, can produce. Lord Justice BOWEN said on a recent occasion that to teach the rising generation how to snatch greedily at mental improvement, with the sole purpose of disposing afterwards at a profit of what they learn, is to narrow and injure education; and, quoting from PLATO, he added, "the sort of instruction which aims at the acquisition of wealth or of mere cleverness is illiberal and mean, and unworthy of the name of education."

With these reservations, which we feel to be necessary when one of the older Universities thus stoops to compete with technical colleges, we continue to wish every success to the Engineering Laboratory at Cambridge, and feel sure that in the mathematical atmosphere of the place, under the warm influences of the ardour of research and genial financial showers, the dry problems of inextensible cords on frictionless pulleys will ripen into life, and fruits comparable with those of the other Cambridge laboratories will be brought forth in due season. In his introductory lecture delivered at Cambridge two years ago, in concluding a review of the engineering laboratories of this country, Prof. EWING said that the services rendered by Prof. KENNEDY at University College would not soon be forgotten. "He found the engineering laboratory no more than a means of private research. He left it an instrument of education." After our rather coldly critical attitude towards the teaching of engineering at Cambridge, we gladly congratulate Prof. EWING on his views of the object of a laboratory. It has been suggested, nay even urged, that a professorial chair is of so little pecuniary value in itself that the use of a well equipped private laboratory is but a fair reward or bait whereby the services of an able professor may be retained. There seems little fear that Prof. EWING will regard his laboratory in this light, and we repeat the hope, which we expressed on a former occasion, that it may find some generous benefactor as did the Cavendish Laboratory in the Duke of DEVONSHIRE.

THE FORTHCOMING INTERNATIONAL ELECTRICAL CONGRESS AT CHICAGO.

The following is an abstract of the report of the Sub-Committee appointed by the American Institute of Electrical Engineers, to consider a provisional programme for the International Electrical Congress of 1893. The Sub-Committee consisted of Prof. W. A. Anthony and Messrs. Carl Hering and A. E. Kennelly.

To begin with, the Sub-Committee recommends the ratification of the units, terms, symbols, and definitions adopted by previous International Electrical Congresses, as a mere matter of form and an act of courtesy to preceding Congresses.

New Units.

The Sub-Committee is aware that objections are raised by some to the establishment of units not already in universal use. Past experience, however, has, they state, shown that the proper time to establish units is *before* their need is universally felt, in order to avoid the introduction by different persons or nations of units of different values, a contingency very likely to arise if not anticipated by concerted action.

The following recommendations are made:—

The value of the practical unit of magneto-motive force to be one-tenth of the absolute unit, that is, equal to $1/4\ \pi$ ampere turn. The value of the practical unit of magnetic flux to be 10^8 absolute units or lines. The value of the practical unit of magnetic intensity to be 10^8 absolute units, that is, 10^8 lines per square centimetre. The value of the practical unit of reluctance to be 10^{-9} absolute units. The value of the practical unit of electrical conductivity to be 10^{-9} absolute units, that is, the reciprocal of the ohm. The value of the practical unit of illumination to be a bougie-decimale at the distance of one metre.

It having been announced that a proposition will be made at the Congress to change the values of some of the practical units which have been adopted by previous Congresses and are already in universal use, among these being the ampere and the farad, it is urgently recommended that such changes should not be favoured, since they would necessarily be followed by great confusion, and would of necessity have to be accompanied by some change in these well established names in order to distinguish the new units from those now existing.

Names for Units.

The following new names are suggested:—

For the practical unit of magneto-motive force, the name "gilbert." For the practical unit for magnetic flux, the name "weber." For the practical unit of magnetic intensity, the name "gauss." For the practical unit of magnetic reluctance, the name "oersted." For the practical unit of inductance, the name "henry." For the practical unit of electrical conductivity, the name "mho. For the practical unit of illumination, the name "bougie-metre."

It has been suggested to name the units "kilowatt-hour" and "ampere-hour." The Committee, however, recommends that inasmuch as these terms explain themselves, and are not longer than some others in use, to give them special names would burden a system of nomenclature unnecessarily.

Concrete Standards.

The ampere and ohm and volt are defined in the same terms as in the recent Report of the Board of Trade Electrical Standards Committee (see *The Electrician*, December 9, 1892, page 152).

In order to create as little confusion as possible by the introduction of the set of units which are to become the universal standards, and in order to distinguish them readily from the true theoretical or abstract units defined in terms of the absolute units, it is recommended to call the former simply "amperes," "ohms," "volts," &c., or more specifically "standard amperes," "standard ohms," &c., and to call the theoretical units, "true amperes," "true ohms," &c.

The standard candle, it is recommended, shall be taken as equal to the light from a lamp like that known as the Hefner-Alteneck standard amyl acetate lamp, which is to be defined by its dimensions and the height of the flame. The Sub-Committee recommends that no action be taken by the Congress in the matter of a universal wire gauge.

Notation and Symbols.

The system suggested to the last Congress by M. Hospitalier is recommended.

Definitions.

The following definitions are suggested:—

The impressed electromotive force is the ratio of the total activity in an electrically conducting circuit to its instantaneous current-strength.

The inductivity at any point in an isotropic medium is the ratio, added to unity, of $4\ \pi$ times the intensity of magnetisation there existing, to the magnetising flux-density. Inductivity is synonymous with "permeability." The electro-magnetic dimensional formula is $L^\circ\ M^\circ\ T^\circ$; the conventional symbol is μ.

Inductance.—(*a*) Self inductance is the ratio of the total magnetic induction linked with and established by an electric current to the uniform strength of the same. The inductance of a conducting circuit is constant when its environing medium has constant inductivity. (*b*) The mutual inductance of one electric circuit upon another is the ratio of the total magnetic induction linked with the second, due to a uniform current in the first, to the strength of that current. The mutual inductance between two electric circuits is reciprocally equal when the environing medium has constant inductivity. The electro-magnetic dimensional formula is $L^1\ M^\circ\ T^\circ$. The absolute unit is one centimetre; the practical unit, one "henry."

The reluctivity of a medium at any point is the volume differential of the reluctance thereat. Simple definition: Reluctivity is the reluctance per unit volume. The electro-magnetic dimensional formula is $L^\circ\ M^\circ\ T^\circ$. The absolute unit is one C.G.S. unit of reluctance per cubic centimetre; the proposed practical unit is the same or about one "oersted" per cubic earth quadrant.

The resistance of copper known as Matthiessen's standard shall be defined as follows:—The resistance of a soft copper wire one metre long, weighing one gramme, is 0·14365 B.A. units at 0° C.

The north pole of a magnet to be defined as being that which seeks the geographic north pole, and the south pole that which seeks the geographic south pole.

Hosted by Google

Expressions.

The Sub-Committee also suggest the adoption of the following expressions: "simple" alternating current for the usual alternating currents in which there is practically but a single phase; "di-phase" alternating currents for two alternating currents whose phases differ in time by 90 or 270deg.; "tri-phase" alternating currents for three alternating currents whose phases differ in time by 60 or 120deg.; "poly-phase alternating currents for such as have more than three phases.

Universal Use.

The more universal use is recommended of the term "voltage" as synonymous with "difference of electrical potential" or P.D., in place of the terms "potential," "tension," or "pressure," the use of which in this sense it is recommended to abandon; of "transformer" instead of "converter"; of "dynamotor" for a continuous current transformer; of "continuous current" instead of "direct current"; of "kilowatt" instead of "horse-power"; of the metric system of weights and measures.

Programme.

Regarding the programme for carrying out the work, it cannot be too strongly urged, the report states, that an International Congress is the place to close, but not to open a discussion on questions about which international agreement is to be had; it is therefore urgently recommended that action be taken at once to open the discussion of such matters now, in order that expressions of opinions, and, if possible, agreements, may be arrived at prior to the meeting of the Congress. To this end the Committee recommends that the suggestions embodied in the report be printed and sent to all the leading electrical and physical societies and journals in America and abroad, with a request that they aid this work by making them public, by freely discussing them, and by sending copies of such discussions and any further suggestions to the General Congress Committee of the Institute, care of the Secretary, 12, West Thirty First-street, New York City. It is suggested that a sub-committee of the Institute should prepare from time to time a classified summary of such discussions and send them to the leading electrical and physical journals for publication and present a final summary of this international discussion at the Congress. It is recommended also that the Institute should invite other societies to co-operate with it by appointing special committees to discuss and report to their respective societies on these international questions and to publish their conclusions in the electrical journals of their country.

Meetings.

Regarding the meetings of the Congress, it is recommended that, as in the Paris Congress of 1889, the meetings be divided into (*a*) *General Meetings*, one at the opening and one at the closing of the Congress, to be devoted to the consideration of general questions and those on which agreements are desired, and to the reading of papers of a general character; (b) *Sectional Meetings* for the reading of all other papers.

Papers.

It is suggested that specific invitations be extended by the Congress Auxiliary to prominent electrical engineers and physicists to prepare papers on specified subjects to be read and discussed at the Congress meetings. Also that a general invitation be extended for other papers, which are to be submitted, not later than July 15, 1893, to a committee on papers appointed by the Chairman of the Congress Auxiliary. The Committee suggests that papers should be solicited by the General Congress Committee of the Institute on the work of the early electricians of America and other countries, considered from a modern standpoint, and their importance in the development of the science of electricity, including descriptions and illustrations of models and apparatus used.

Membership.

It is suggested, in conclusion, that the membership of the Congress be divided into delegated members and members; that the fees for each shall be $5; that only delegated members and members be admitted to the meetings, and be permitted to take part in the discussions; that anyone shall be entitled to become a member; that delegated members shall be appointed by governments, physical and electrical societies, and shall be approved by an international committee, whose decision shall be final; that questions on which international agreement is desired by the delegated members, whose decisions shall be submitted to the whole Congress for approval or rejection in part or in whole, but not for alteration.

INSTITUTION OF ELECTRICAL ENGINEERS.*

MR. PREECE'S PRESIDENTIAL ADDRESS.

Telegraphy.

The instrument that we have principally developed in England is the automatic fast-speed apparatus, based on a principle of preparing messages for transmission by punching, devised by Alexander Bain in 1848, and improved in its mechanical details by Mr. Augustus Ströh in 1866. This has been my special pet, and with the electrical assistance of Mr. J. B. Chapman, and the mechanical skill of Mr. J. W. Willmot, all the ills that telegraphs are heir to have been routed, and the practical speed of working has been multiplied more than six-fold. We have, step by step, won all along the line: 75 words per minute have become 500; a possible 130 has become an actual 600. Duplex automatic working over cable lines is possible, and modes of working have been introduced that were thought at one time chimerical and impossible. All these things have been done without recourse to the Patent Office. The Hughes typewriter has this year been successfully duplexed between London and the Continent, a problem which had hitherto baffled all attempts at a satisfactory solution.

One of the arguments used against the proposed transfer of the telegraphs to the State was the notion that invention would not be fostered by a Government department. This has been entirely falsified. Telegraphy has been advanced in this country more rapidly by the British Post Office than by any private undertaking, and we have certainly shot ahead of our smart cousins on the other side of the Atlantic, from whom, however, I am proud to say, I learnt so much on my visits in 1877 and 1884. An accident in the drafting of the Act of Parliament of 1868-69 transferring the telegraphs from the hands of private companies to that of the State, has led to a tremendous development of newspaper reporting in England. Few people are aware of the immense business done for the Press. When Mr. Gladstone spoke at Newcastle, at the National Liberal Federation, in 1891, 390,778 words were signalled to different parts of the country. The news transmitted is chiefly commercial and financial, amounting to 2,775,000 words per day. We public servants rely on public criticism, andour sole object is to serve our masters, with a conscientious determination to do our duty to the best of our ability.

Submarine Telegraphy.

The growth of submarine cables about the world is extraordinary. The total mileage, which in 1852 was 87 nautical miles (nauts), now reaches a total of 139,594 nauts, of which 14,479 nauts belong to various Government administrations. Between this country and the Continent all the cables (with the exception of those to Norway, those to Spain, and those forming the connections with the Eastern Telegraph Company's system) now belong to the respective Government administrations, and are all maintained by them. The British Post Office owns and maintains those to Holland and one of those to Germany, while those to Belgium and France, containing 37 wires, are joint property, but maintained by the British Post Office.

Next to strong tides, rocky bottoms, anchors, and shallow water, the greatest enemy to submarine cables, more especially in the tropics, has proved to be the teredo of various species; but this depredatory worm has been utterly routed by covering the gutta-percha core with a lapping of thin brass tape laid on spirally. A remarkable thing about this little insect is that, whereas 20 years ago it was practically unknown in our English waters, it has now gradually spread all round our coasts, with the exception, perhaps, of the North Sea. A new cable about to connect Scotland and Ireland is being served with brass tape. Perhaps the most remarkable history of a cable is the following:—In 1859 the light cables laid in 1853 from Orfordness to Holland were picked up and replaced by a heavier one. A few nauts were sold to the Isle of Man Telegraph Company, and had an extra sheath laid on. This cable was submerged between that island and St. Bees, where it remained until 1885, when it was replaced by a three-core cable. It was again put under water in 1886 as part of the cable between Uist and Harris, in the Hebrides, where it still lies, as good as ever. The durability of submarine cables is remarkable. That laid between Beachy Head and Dieppe in 1861 is still working, and

* Abstract of an address delivered January 26, 1893.

Hosted by Google

that laid between Beachy Head and Havre in 1870 has broken within the last month for the *first* time.

Lightning Protection.

There is no more perfect apparatus in existence than the lightning protector. In 1892 not one single accident was recorded to any high-class telegraph instrument in the whole of the United Kingdom.

Railway Signalling.

The enormous development of electrical engineering upon our railways is shown by the following return from one system only :—

Midland Railway Telegraph Plant, December 31st, 1892.

Approximate.

* Exclusive of P.O. wires.

Telephony.

The demand for communication between distant places has necessitated the application of much special attention to the method of constructing lines and of arranging circuits. It is in this latter field that I have been a diligent worker, and the application of the so-called "K R" law has proved of material benefit in connection with the problems of long-distance telephony. It is a law which implies that the number of signals that can be transmitted per second through any circuit depends solely on the capacity (K) and the resistance (R) of the circuit. It is very much the fashion to deny the accuracy of the K R law. This is probably the result of ignorance of its meaning or of its interpretation. Some speak of it as empirical, others scoff at it as imaginary, and some sneer at it as an impossible law ; but it is a law that has determined the dimensions and speed of working of all our long submarine cables ; it determines the number of arms a circuit can carry on the multiplex system, the speed attainable with the Wheatstone system, and the distance to which it is possible to work quadruplex ; it is a law that has enabled us to bring London and Paris within clear telephone speech of each other, and which will probably before the year is out enable Dublin and Belfast to speak to London—a message of peace to Ireland as solid and substantial as any promised political proposal. The New York and Chicago trunk line is 950 miles long, and it is built with 435lb. (or No. 8 S.W.G.) copper wire. This wire gives a resistance of 2·06 ohms per mile, which is easily verified ; but it is said by Mr. Wetzler to have a capacity of 0·0158 microfarad per mile, which cannot be verified, and which is absurdly high. 0·0158 microfarad was a measurement made by me in England on an old line, but I have frequently pointed out that owing to the use of earth wires the capacity of our English lines is very much greater than that of American lines. Mr. Edison discovered this in 1872 when he came to England to introduce his automatic system. Moreover, I have also pointed out that induction still further diminishes this capacity. The Paris circuit does not exceed 0·005 microfarad per mile. I should estimate the Chicago circuit at 0·004 microfarad per mile, and the K R at 7,500, which gives a result that quite accords with the opinions that I have heard expressed by those who have tried the two circuits as to the relative efficiency of the Paris and Chicago lines. My American friends would have done better if they had used thicker wire. I should have specified 600lbs. per mile ; but if it had been in England I should have used 1,000lbs., for we cannot dispense entirely with cables and underground work as they have done in the States, and the increased capacity introduced must be compensated for by reduced resistance. As a matter of fact, I once proposed 1,200lbs. wire for a circuit between London and Berlin—a distance of 760 miles, including a cable 55 miles long.

The beneficial effect of induction as a negative capacity is observed when working a circuit telegraphically with automatic high-speed apparatus. Thus, on two copper wires 450 miles long, making 900 miles altogether, the speed on each single wire was 120 words per minute, and on metallic circuit—

Loop *viâ* different routes.....120 words per minute.
„ on same poles.....150 „ „

So that the improvement effected by induction was 25 per cent.

There is no difficulty in measuring R of a metallic loop. The Wheatstone bridge determines it at once. There is more difficulty in obtaining K. It cannot be measured directly. But with a metallic loop of copper, partly overhead and partly underground, there are several modifications required, due to electrostatic and electro-magnetic induction, which are at present beyond the reach of formulæ, and render it difficult to determine the capacity except approximately from the telephonic effects themselves. Thus the capacity on the London-Paris circuit proved to be only one-half of that obtained by calculation, and every long circuit will require its own K to be determined by comparison with an empirical K R scale. Such a scale I have determined by careful experiment on artificial cables. I have recently devised a new form of cable, which will probably quadruple the rate of telegraph working to America ; and I may say with all confidence that there is no theoretical reason whatever why we should not converse between London and every capital in Europe, while it is not impossible to speak even across the Atlantic.

Electro-Chemical Industry.

The electro-chemical industry is, financially, one of the most important in this country. Electro-plating was started by Elkington at Birmingham in 1840. There are now about 170 electro-platers in Sheffield, and over 100 in Birmingham. Christophle, of Paris, deposits annually six tons of silver. An interesting process, by which phosphorus was separated from corundrum, a mineral phosphate, by the dissociating effect of the terrific heat of the electric arc, was developed by Readman, Parker, and Robinson, at Wednesfield, near Wolverhampton ; but though the right to use this mode of producing phosphorus was purchased at a very high figure by those who have the monopoly of that business, it does not appear that it has been put to practical use at present.

Electric Lighting

The cost of wiring is a great deterrent to the introduction of the electric light into small tenements and into houses held on short tenures. The materials used must be of the most perfect kind, otherwise insecurity is incurred ; but there are expensive practices of wood casing and of ornamentation which want reform. The Cheap Jack is the curse of the industry, and the absence of specification and of inspection the danger of the user. The early pioneer alternate-current systems, which have done so much to further the development of electric lighting, were, however, costly in their coal bills, owing to great losses of energy in their iron and copper ; but the transformer of the present day is as perfect in efficiency as the dynamo. These losses have practically disappeared, and modes of switching transformers in and out at will have removed every difference of cost between high pressure and low pressure systems. The prejudice against high pressure is still strong, but time and experience will eradicate it as they ultimately eradicate every fallacy. The prejudices against high-pressure steam and against high speed on railways were once equally strong ; but those prejudices survive only as "bees in the bonnets" of a few.

If a full load could be maintained during the whole 24 hours, electrical energy could be manufactured for one-third of a penny per supply unit, and this is equivalent to gas at 2d. per 1,000 cubic feet. The potentiality of economy in electric lighting is thus beyond the dreams of the gasman.

Water power abolishes the coal bill, but it must be remembered that the cost of maintenance of machinery and of the erection and upkeep of conductors limits the distance to which the energy of falling water can be economically transmitted. The proposal to light New York by currents generated at Niagara is at present financially absurd. It is doubtful whether it will be commercially advantageous at Buffalo, 30 miles away, but it is certain that at Tivoli it can be so applied with advantage and profit.

Electric Traction.

The use of electrical energy for working railways is making gigantic progress in the United States, and has commenced to make a serious move in the United Kingdom. The City and South London Electric Railway has proved a decided success, and next week will record the opening of a still larger enterprise on the elevated railway of the Mersey Docks in Liverpool. When last I visited America, in 1884, there was only one electric railway in work, and that was in Cleveland. One company alone, the General Electric Company of the United States, working the Thomson-Houston and Edison systems, has now—

Road in contract and under operation	440
Cars	8,856
Miles of line in operation	4,628

Thus the average length of electric railway is 10·5 miles, and the average number of motor cars in use about two per mile. The power used is over 100,000 H.P. Speeds of 40 miles an hour are sometimes obtained in the open country, but in the crowded streets this rate is much reduced. All these railways are worked with overhead conductors, by what are known as trolley lines. Such a line is at work in Leeds, and the South Staffordshire tramways have just started the same practice. Considerable experiments have been made to work tramcars by accumulators carried on the

Hosted by Google

car. They have met not with much success, owing to the cost of renewals. The Birmingham Central Tramways are, however, persevering in this direction, and they are now giving an extensive trial to a new form of accumulator—the Epstein—the proprietors of which have adopted the novel plan of undertaking to renew the accumulators at the rate of 1½d. per car mile.

Theory.

In the Presidential address which I delivered to the Society of Telegraph Engineers and Electricians in 1880, I took the opportunity to formulate the theoretical views of electricity that I had acquired at the feet of Faraday. It is not given to every boy to have his great ambitions realised. One of my ambitions as an earnest listener to Faraday's simple and delightful lectures was to be his assistant, and in almost the last investigation he undertook on electric induction in underground wires it was my privilege to see much of him, and to prepare many experiments for him. Early in 1854, at his wish, I carried out for Mr. Latimer Clark certain experiments on the comparative effect of increments of voltage in increasing the rate of transmission of signals through long telegraph circuits. It was found that variation of voltage had no effect. Currents from 31 and from 500 cells sent through 768 miles of gutta-percha-covered underground wire showed precisely the same velocity. These experiments were sent by Faraday to Melloni, who had prompted the wish, and Melloni ("Faraday's Researches," Vol. III., p. 577) remarked: "The equal velocity of currents of various tensions offers a fine argument in favour of the opinion of those who suppose the electric current to be analagous to the vibrations of air under the action of sonorous bodies." This is to be found in the very last contribution inserted in the greatest work ever published on our science, "Faraday's Experimental Researches in Electricity." Faraday's views were subsequently expounded and extended by Maxwell, who said: "Faraday, in his mind's eye, saw lines of force traversing all space, where the mathematician saw centres of force attracting at a distance; Faraday saw a medium where they saw nothing but distance; Faraday sought the seat of the phenomena in real actions going on in the medium, they were satisfied that they had found it in a power of action at a distance impressed on the electric fluids" (Maxwell, "Electricity," Vol. I., p. 10). Since that period I have never regarded electricity as anything else but as a form of energy, and its effects as modes of motion of the molecules of matter and of the ether that fills all space; and during my long apprenticeship of 40 years I have never examined one experiment or considered one fact that was not explicable on this theory.

It must be distinctly understood that I apply the term *electricity* to that form of energy which we as engineers utilise in the service of man. I do not apply it, as some physicists do, to a mere imaginary factor of this energy, sometimes called "quantity," and even honoured with a unit—the *coulomb*. I use it in the same sense that we use the terms *light*, *heat*, and *sound*, which are universally acknowledged to be forms of energy. In my address as President of the Mechanical Section of the British Association at Bath in 1888, I pointed out the great confusion that arose from this misapplication of terms, and I suggested that the disturbing factor—the vague subjective unreality of the physicist—might be called by some other term. I now go further, and suggest that the term be abolished altogether. We can do without it. It is not wanted. We have excluded the coulomb from our new legal system of C.G.S. units.

It is a misfortune that a beautiful hypothesis like Maxwell's electro-magnetic theory of light has been discussed almost solely by mathematicians. Its consideration has been confined to a small and exclusive class. It has not reached the public; and this is to be regretted, for after all it is the many, and not the few, that determine the acceptance or refusal of a theory. The existence of the ether is now thoroughly comprehensible. Light is now regarded as an electro-magnetic disturbance. The eye is an extremely sensitive and delicate electro-magnetic instrument. The difference between luminous, thermic, and electro-magnetic waves is one of frequency and form. We thus have to consider the propagation of these waves, not only in the conductor and in the dielectric in the direction of the circuit itself, but in the ether at right angles to this direction. The former produces currents in the conductor, and the latter induction and secondary effects in contiguous conductors. Thus it is easy to see why electric and magnetic lines of force are at right angles to each other, and each of them perpendicular to the line of propagation of the primary electro-magnetic wave, and why the transversal disturbances are secondary waves of electro-magnetic energy which can be transformed into electric currents of opposite direction whenever contiguous conductors lie in their path so as to be cut by these lines of force in the proper direction. Induction is thus mere transformation of energy whose direction and magnitude are easily calculated.

It is by following out this line of thought that I have recently succeeded in sending messages by Morse signals across the Bristol Channel between Lavernock and Flat Holm, a distance of 3·1 miles. The electro-magnetic disturbances were excited by primary alternating currents in a copper wire, 1,237 yards long, erected on poles along the top of the cliff on the mainland. The radiant electro-magnetic energy was transformed into currents again in a secondary circuit, 610 yards long, laid along the island. The strength of these secondary induced currents complied almost exactly with calculations. The results attained, the apparatus used, the precautions taken to separate effects of induction from effects of conduction; the elimination of mere earth currents from electro-magnetic disturbances in air, will form the subject of a separate Paper, for their proper consideration would be too tedious for an address. I allude to them now only to illustrate the existence of one of the greatest proofs of the truth of a theory, viz., the practical development and verification of a conclusion predicted from mere theoretical considerations.

The advance of our knowledge in this branch of electrical development has been very much retarded by the phantasies of visionary mathematicians who monopolise the columns of our technical literature and fill the mind of the student with false conclusions. I have no sympathy with the pure mathematician who scorns the practical man, scoffs at his experience, directs the universe from his couch, and invents laws to suit his fads. The American, in his quaint, humorous way, said, "Theory without practice is absolutely a worthless commodity; practice without theory is worth about 15 dollars a week; but when both are well combined in one man of sound judgment, the combination is worth up to 10,000 dollars a year."

My sympathies are with the earnest worker who asks Nature direct questions by sheer experimental prodding, who elicits from her stronghold the secrets of her prison-house, who presents gratuitously to the world the efforts of his labours in plain language, and who is willing modestly to follow in the footsteps of his great masters—Faraday, Maxwell, Kelvin, Von Helmholtz, and Rayleigh. Such men are to be found on both sides of the Atlantic. Our own proceedings chronicle the work of Hertz, Tesla, and Elihu Thomson. I must not exclude the teacher, the much-abused professor, who combines practice with theory, and who, in our technical institutions, is training up a body of youths destined to carry on the great work in the future. Amongst these able men there is no one who has earned a more richly deserved reputation than my predecessor in this chair (Prof. Ayrton).

Conclusion.

Although my practical experience extends over 40 years, my personal reminiscences commence with the reign of the Queen, and are, therefore, coincident with the Victorian era. Progress is advancing with such rapid strides that, when the time comes for my son to chronicle to some institution of ethereal engineers his experience of 50 years' observation, the people of his day may look back with pity and amusement at the backwardness of the times of 1893. Even this address may be quoted as an illustration of the ignorance of the great Victorian period.

Cannot the electrical engineer claim some share in the progress of the world? Has he not annihilated space and bridged the ocean? He has extracted the precious metals from their stony bed, and brings to our very hearths the tamed energy of the roaring torrent. Commerce, civilisation, politics, and life have all been benefited by his skill and invention, and history cannot fail to record the names of those, among whom are many members of this Institution, who, in this great Victorian era, have done so much to discharge one of the highest duties of man, the fulfilment of the functions of the true engineer.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORE UNWIN, F.R.S.

Water Power Storage.

Prof. Unwin commenced by saying that he must add a word or two to complete his last lecture on the special conditions of power storage in water power systems. The need of storing power derived from waterfalls arose out of different considerations from those which applied in the case of steam power. A river flowed day and night with an energy which varied seasonly but not from hour to hour. The work to be done necessarily in some cases varied, and in by far the larger number of cases there was no demand for work to be done during the greater half of the twenty-four hours. If no means of storage were found, a large part of the natural supply of energy flowed away and was wasted. But there was another reason in the case of water power for using storage. Nearly the whole cost of water power was due to interest and depreciation on the

* Abstract of third Howard Lecture delivered before the Society of Arts January 27th.

Hosted by Google

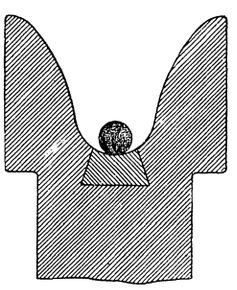
permanent works, machinery and structures. Nearly nothing was due to daily working expenses. With steam power only about one-third to one-half of the cost was due to permanent charges, and the rest of the cost arose out of wages and fuel. If water power machinery stopped for twelve hours out of the twenty-four there was no sensible diminution of the working expenses, and the cost of horse power was doubled. It would appear in the course of the lectures that the most characteristic advantage of water power as compared with steam power was that the former permitted the use of storage of energy by means neither complicated nor difficult.

There were two distinct methods of storage in hydraulic systems, accumulator and reservoir storage. Perhaps, on superficial consideration, it would hardly appear likely that it would be profitable to pump water to be used for power purposes. There were cases, however, where it was so. One of these was the system of hydraulic transmission originated by Lord Armstrong. The system of hydraulic transmission was used, and could only be used, advantageously to work a great number of intermittently working machines. A single engine, working nearly continuously, pumps water which actuates a great number of intermittent motors, in which the fluctuation of demand varies a great deal, especially from minute to minute. Storage in that case was essentially necessary. Perhaps it was the invention of the accumulator, a means of storing the energy of pressure water, that the success of the hydraulic system was mainly due. The hydraulic accumulator was simply a vertical cylinder, with a heavily-loaded plunger, into which water was pumped. One very large accumulator of the London Hydraulic Power Company, the diameter of which was 20in., the stroke 23ft., and which worked under a pressure of 750lb. to the square inch, large as it was, stored only 2·4 H.P. hours, a very insignificant quantity. What made an accumulator so important was that its rate of discharge was very great. The accumulator he had mentioned would probably supply 100 H.P. for 1½ minute, hence, like the flywheel, the use of the accumulator was limited to regulating for short periods of time, and could not be used to average the variation of demand during the twenty-four hours.

If a suitable site could be found reservoirs could be built of very large capacity at a cost which would not be large per unit stored. At Zurich, for instance, where they pumped water for power storage, there was a reservoir of a capacity of 353,000 cubic feet at an elevation of 475ft. That reservoir stored 5,284 H.P. hours. That was enormous as compared with the storage in an accumulator. Both at Geneva and Zurich very remarkable and expensive systems for utilising and distributing water power had been for some time in successful operation. In both cases water flowing out of a large lake with comparatively small fall was utilised to furnish a very considerable amount of power. In both cases it was found convenient and economical to use the low pressure turbines in the river to pump water to a reservoir at a great elevation, and use the pumped water for motive purposes. At Geneva the Rhone was made to afford a clear fall varying from 5½ft. to 12ft. There had been, or shortly would be, erected 18 low pressure turbines giving an aggregate power of over 4,000 H.P. A reservoir was constructed 390ft. above the lake capable of storing, allowing for loss in motors, 4,180 H.P. hours. The reservoir was a covered reservoir of expensive construction, but he found that its cost did not exceed £2. 4s. per H.P. hour stored. It required very little maintenance, and he supposed it did not add 3s. per annum to the cost of horse power supplied. On the other hand, the energy stored would, without that reservoir, have gone to waste, and the energy saved was sold for £8 per horse-power per annum.

Telodynamic Transmission.

The first method of transmission of power to any considerable distance was by wire rope. Telodynamic transmission was first applied by M. Hirn in connection with the re-opening of idle factories at Logelbach, near Colmar in Alsace, in 1850. One of the factories was worked at a distance of 80 metres from a steam-engine, by a steel band on wooden pulleys 2ft. in diameter, the steel band being about 2½in. wide. This was used for eighteen months, transmitting 12 H.P., when an English engineer, Mr. Tregoning, suggested the use of a wire rope cable ¼in. diameter. The same pulleys were used, a groove being turned in them to carry the cable. That cable worked for years; but iron pulleys were substituted for the wooden ones. A second transmission was soon erected with pulleys 10ft. in diameter and a cable ½in. in diameter. M. Hirn confessed that the chief difficulty was the construction of the pulleys, and it was not until he had adopted a dove-tailed groove, bottomed with gutta-percha, so as not to wear the rope, that the problem was solved. The cables were at first of iron, but were now of mild steel; the largest was about an inch in diameter, and the pulleys were from 12ft. to 15ft. in diameter, and in the throat of the pulleys there was a dove-tailed groove, which was filled up with gutta-percha, strips of pine wood, or bits of old leather or canvas belting, the last, he believed, being best. The power transmitted was equal to the product of the tension into the speed. The maximum speed was about 100ft. per second, and a one-inch rope running at that speed could transmit 330 H.P. The pulleys were usually from 300ft. to 500ft. apart. In 1862, M. Hirn stated that he knew of 400 cases of wire rope transmission. The largest telodynamic rope in existence was one constructed by Messrs. Rieter of Winterthur, the rope used being six stranded, and each strand consisting of six wires. There was a hemp core for the whole wire, and each strand also had a hemp core, thus making the rope more flexible. The longest transmission he knew of was at Freiburg, the distance being just over a mile (6,500ft.). M. Hirn had hoped to make his wire cables last a very long time indeed, eight or ten years at least; but that had proved not to be practicable, for they had not been found to last for much more than a year. A little difficulty had been found with the stretching of the rope when first erected, but that was got over by passing it several times through grooved rollers with a considerable pressure before erecting it. As the supporting pulleys were expensive, and were a cause of waste of power, it was desirable that the spans should be large, and spans of from 300ft. to 500ft. had been adopted, and as this led to a considerable deflection of the cable, the pulleys must be placed high enough to keep the wire off the ground, the slack side in some cases having additional pulleys.



The two principal sources of loss of work with telodynamic transmission were the friction of the journals supporting the pulleys and the resistance due to stiffness of the rope. Zeigler's experiments gave for the friction of the journals 1·14 H.P., and for the work expended in bending the rope 0·625 H.P., a total of 1¾ H.P. at each pulley station. When transmitting full power the efficiency of the system was remarkably high (0·962 for each pulley station); there was no other mode of transmission to corresponding distances involving so little loss of work, except electrical transmission.

Telodynamic Installations.

At Oberursel, near Frankfort, there was an important cable transmission installation for supplying from 64 to 154 H.P. to a cotton mill. The fall above the mill was about 264ft., but was at such a distance that it could not have been utilised by ordinary means of transmission. Two tangential impulse wheels were erected, and the power was transmitted to a distance of 3,160ft. in seven spans, the diameter of the rope being ⅝in. Another important transmission arose in a curious way. In 1864 there was an explosion in a gunpowder factory at Ochta, near St. Petersburg, and it was determined to reconstruct the factory and work it by means of wire rope transmission, in order to secure the condition that the dangerous buildings should be at a distance from each other.

The best known instance of wire-rope transmission was probably that at Schaffhausen. After a period of great trade depression there was a revival of industry in the town between the years 1840 and 1850. In the last-named year Herr Heinrich Moser, of Charlottenfels, constructed a canal, and erected the first turbines at Schaffhausen. It then occurred to him that it might be possible to render useful the immense volume of water passing through the town, and the extraordinary winter of 1857 and 1858 favouring an examination of the bed of the river, the erection of a weir across the river was suggested, and the construction of a power house on the right bank, with turbines of 500 H.P. on a fall of 6ft., and transmission of power across the river to the factories on the left bank of the river. A company was formed in 1864 to carry out the works, and the weir was constructed during favourable seasons. The turbine house contained three turbines of 200 H.P., 260 H.P., and 300 H.P.; they were ordinary low pressure axial flow turbines, with vertical shafts driving horizontal shafts. There was a transmission of 200 H.P. to factories on the hill above the turbines. From the same shaft about 22 H.P. was taken off by a subsidiary wire rope transmission, which passed down the right bank, and a small transmission went across the river. There remained about 530 H.P. to be dealt with by the main wire rope transmission which passed directly across the river. The principal transmission across the river was by means of two cables, with a single span of 385ft., the diameter of the pulleys being 15ft., running at 80 revolutions. The two principal rope driving pulleys were not keyed on the horizontal driving shaft, but ran

Hosted by Google

loose on it. If the tension of either of the two driving cables varied, the bevelled gearing revolved and equalised the strain. The gross power in the horizontal driving shaft in the turbine house was about 530 H.P., or, allowing for friction, 500 H.P., 250 H.P. for each rope. The ropes were 1in. in diameter, and ran at a speed of 62ft. per second. Either rope was capable of transmitting a large fraction of the whole power. Perhaps the most interesting feature was the single line, which transmitted an aggregate of 27 H.P. to ten small workshops The Schaffhausen installation had been an entirely successful undertaking, and had very greatly benefited the industries of the town. In the year 1867 there were only 13 renters of the power, who paid an annual rental of £345. In 1887, the latest date to which he had details, there were 23 renters, paying to the water power company an annual rental of £3,300. The charge for power in 1887 varied £4. 16s. to £6 per horse-power per annum delivered at the mill. The total cost of the work appears to have been reckoned at £29,360 originally, and this, by writing off, stood at £24,634 in 1887. There was a greater loss of power in wet and frosty weather than was originally anticipated. A spinning factory had complained that the running was not so regular as they would like, and this led to the construction of a new power station, and the adoption in the new works of electrical instead of wire rope transmission. In some excellent lectures delivered before that Society in 1891 by Mr. Gisbert Kapp, the method of transmission by wire rope was compared with the method of transmission electrically, very much to the disadvantage of the cable transmission. "Till recently," said Mr. Kapp, "rope transmission held the field absolutely, not because it was perfect, but because there was nothing better. Now, however, we have something better in electrical distribution, and the flying ropes are being steadily replaced by the electric conductors." The use of the words "steadily replaced," the lecturer thought, was based upon a wrong impression. The wire ropes had not been replaced at Schaffhausen by electrical conductors, but an additional power station had been erected, and electric transmission had been placed alongside cable transmission. It happened accidentally that at the only visit he (the lecturer) had made to Schaffhausen in recent years the rope transmission was working perfectly, while the electrical transmission was *hors de combat*, the motor having been burnt up by a lightning discharge.

A very interesting transmission was begun at Freiburg in 1870, when a company was formed partly to acquire and work the forests near the town, partly to utilise and sell water power, and partly to carry out a scheme of water supply. A dam 40ft. high was constructed across the river Sarine, in a ravine where it was impossible to erect factories; about 300ft. above the ravine the company acquired some level land. There was an effective fall of 35ft. and an available 1,700 H.P. The system was working perfectly well, and power was sold at the rate of £8 per horse-power per annum. Girard turbines were used. In 1872, a company was formed to utilise the water power of the Rhone some distance below Geneva at Bellegarde. The total power available was estimated at 12,000 H.P. The original project, which was on a very large scale, had been only very partially carried out, and the working was not very successful. The power was sold at from £8 to £12 per horse-power per annum. There were five Jourdan turbines capable of developing 630 H.P. each, and a wood pulp factory, a butter mill, a copper refinery, and othes works were now driven by these turbines. The turbines were in a very deep gorge, and the distance to the farthest factory was 3,000ft. The greatest span was 630ft., and the largest ropes were 1¼in. diameter, the largest he knew of; the speed was 66ft. per second. He (Prof. Unwin) visited Bellegarde some little time ago, and though the whole of the transmission was working, it had that aspect which places got which were not paying a sufficient interest on the capital expended; the works were not kept up as well as they might be, and there was grumbling on the part of the consumers that the water company were not doing as much as they ought in repairing the turbines and so on. This was a case where they went to a new country and expected the factories to come to them. There were no actual works on the spot, and the factories did not come fast enough, and the power company got more or less into arrears in the payment of interest on the capital, and so the thing had not succeeded; but at the same time mechanically there had been no failure.

The most recent, and one of the largest installations of telodynamic transmission, was at Gokak, in the Southern Mahratta Country, which was carried out by MM. Escher and Wyss, of Zürich. The river fell over a high cliff, and had motive power enough for many industries. There were three turbines of 250 H.P. each, and these drove a cotton mill of 20,000 spindles. The total fall acting on the turbines was 180ft.; the turbine wheels were 67in. in diameter, and ran at 155 revolutions. They were impulse turbines, with partial admission, on horizontal axes, each turbine axle carrying a driving pulley. There was a sluice valve worked by hand, and a disc valve controlled by a relay governor to each turbine. The shafts of the turbines carried wire rope pulleys 11½ft. in diameter, the rope speed was 93ft. per second, and the ropes 1in. in diameter. There were three ropes, one from each turbine. The installation had been perfectly successful. He heard they were going to double the power, and in the new transmission were going to try electric transmission. There were two reasons for that, one being that in India they wanted experience in comparing the two systems under conditions in which they could get exact data about each, and the other that if they adopted rope in the new transmission they would have to carry the ropes underneath the existing transmission.

El-ctric and Telodynamic Transmiss on compared.

The telodynamic system was adapted to the transmission of power to distances which were large when compared with the distances to which power was ordinarily transmitted; but it could not seriously compete with electrical transmission in cases where the distance to be covered was reckoned by many miles. It had the peculiar advantage that it transmitted the energy developed by the prime mover directly, whereas in electrical distribution there was a double transformation. The efficiency of transmission to such distances as those at Schaffhausen was very great; it was uncertain whether a similar amount of power could be distributed to an equal number of consumers electrically with less waste of energy in the process. Then the telodynamic transmitters, which had been at work, some of them, since 1864, had been at work continuously without serious stoppage, and had only failed to return an adequate profit where they had been undertaken on a scale too large for the amount of industry requiring to be supplied with power. On the other hand, it might be admitted that telodynamic transmissions, simple as they were mechanically, involved considerable cost. The cost of maintenance of the cables was great; they had to be replaced annually, and experienced workmen had to be employed to make the long splices in the ropes. One disadvantage of the telodynamic system was that no means were to be found of directly measuring by numerous or continuous observations the amount of power delivered to each consumer. So long as the power was distributed to very few consumers, it was possible to assess with practicable fairness the charge to each without measurements of the power; but in proportion as the consumers became more numerous the difficulty of the system in that respect became more serious. It was not possible by increasing the size of the cable to transmit an indefinitely large amount of power. Cables became unmanageable if the rope was too large in diameter; 300 H.P. was about the limit for a single cable. It was also an inherent characteristic of the cable system that the efficiency decreased rapidly when the distance increased beyond certain moderate limits. On the most favourable interpretation of the experiments made at Oberursal, the efficiency would fall to 0·6 for a 5,000 metres transmission, an efficiency by no means excessively good.

PURIFICATION OF MERCURY.*

BY W. JAEGER.

The method of purification of mercury adopted by the Reichsanstalt for accurate work is worthy of notice. The raw material is the quicksilver supplied by the Idria mines in iron bottles, which is particularly good, and can be used for most purposes after simple filtering. To get rid of the heavy metals the mercury, after filtering and drying, is twice distilled *in vacuo*, during which process care must be taken to avoid every trace of grease and other impurity on the glass or rubber used. For this reason the distilling apparatus is exhausted by means of a mercury pump without cocks, all shutting off being done by mercury; the pump is connected to the still by a glass tube with no cock, which is stopped by melting off when the exhaustion is complete.

After distillation, since electro-positive metals (alkalies or zinc) might still remain, it is deemed advisable to subject the mercury to further purification by electrolysis. As liquid, out of which the mercury is precipitated, a solution of mercurous nitrate is used, which is obtained by the action of nitric acid on an excess of mercury.

Details are given of the electrolytic process employed; and the chemical tests of Dr. Mylins proved that there was no trace of metals except a very small quantity of iron, which probably came from the apparatus used in the test, and there was no residue of any kind after evaporation.

Electricity on Board the Chilian Armour-Clad "Capitan Prat."—Electricity has been adopted on board this warship to a large extent as the motive power in the manœuvring of the guns and turrets.

* Abstract from *Wied. Annalen*, No. 1, 1893, p. 209.

FIRST REPORT OF THE ROYAL COMMISSION ON ELECTRICAL COMMUNICATION WITH LIGHT-HOUSES.

[ABSTRACT.]

The Commission having been issued on June 13th, the first meeting was held on the 18th, and then adjourned until July 19th, by which time charts showing the number of casualties and loss of life on outlying shoals had been prepared, and other valuable information had been obtained. A tour of inspection of lighthouses and light-vessels was commenced on Aug. 15th. The investigations were confined to those points on the coast at which the records of wrecks and loss of life had been heaviest in the last ten years, but much useful general information, together with a considerable amount of local evidence, was obtained in the course of the cruise. Other parts of the coast remain to be visited, but their claims stand over for early investigation, and will be dealt with in a future report. The labours of the Commissioners were greatly facilitated by the assistance received from the Admiralty, the Trinity House, the Commissioners of Irish Lights, and of Northern Lighthouses, the Mersey Docks and Harbour Board, and at Scilly from Mr. Dorrien-Smith. In October further evidence was taken and the first report prepared. It was finally adopted at a meeting on December 8th.

Speaking generally, the need for electrical communication for the purposes referred appears, the Commissioners say, to be greatest in the case of certain light-vessels marking outlying shoals beyond reliable range of the shore for sight or sound signalling. The crews of these vessels, consisting usually of about seven men, keep a regular look-out night and day, and can, therefore, be relied upon to give notice of vessels in distress, which is not the case with lighthouses, where there are only two or three keepers, and where, consequently, a responsible look-out seawards cannot be maintained with the existing staff. On the other hand, in many instances cable communication with these vessels would involve a considerable initial outlay, and although the experiment in the case of the "Sunk" proved that, where the circumstances are favourable, and with the adoption of recent improvements, the difficulty of maintaing communication with such vessels can be overcome, yet, pending further experience, the Commissioners only recommend immediate action to be taken in five cases which appear to be among the most urgent, and where the conditions are comparatively favourable. They also recommend one pile-lighthouse for immediate attention.

With regard to shore lighthouses, there are some which occupy such a commanding position, and can be connected with the telegraphic system at such trifling cost, that they have no hesitation in recommending that these be dealt with at once, for, although no constant look-out is or perhaps could be kept in them, there was evidence that the light-keepers may often be able to give valuable notice of wrecks or of vessels in danger, which could not otherwise be communicated without serious loss of time. The number of such lighthouses is not large, because it is probable that the system of communication with the Post Offices, coastguard stations, Lloyd's stations, and Mersey Docks and Harbour Board signal stations will shortly leave comparatively few important points on the coast unconnected. It is recommended that 19 shore lighthouses be immediately connected.

The case of lighthouses situated on islands or isolated rocks appears, it is said, to present the greatest difficulty. A recent experiment in connection with the Fastnet failed owing to the difficulty of maintaining the cable; but there was evidence to show that is was carried out under unsatisfactory conditions, and that if a similar attempt were made with improved appliances the difficulty of direct communication could be overcome. Three such lighthouses are recommended for connection with a continuous cable.

The experiments lately made at the Needles for establishing electrical communication without a continuous cable may also prove of practical utility. It is recommended that one rock lighthouse should be connected by this system.

Recommendations.

1. Immediate telephonic connection of the Goodwin (North Sand Head), Kentish Knock, Shipwash, Hasborough and Scarweather light-vessels.

2. Immediate connection of the Gunfleet Pile lighthouse.

3. Immediate electrical communication by aërial wires without delay between the telegraphic system of the country and the following 19 shore lighthouses, viz., Start Point, Anvil Point, Needles, Orfordness, Girdleness, Noss Head, Cantick (Orkney), Mull of Cantyre, Corsewall (Stranraer), Mull of Galloway, Douglas Head, Point of Ayre, Nash (both lighthouses), Bull Point, Hartland Point, Minehead (Dungarvan), Hook Point (Waterford), and Bailey (Howth . Of these, two have already been connected, advantage having been taken of the General Post Office engineers being in the vicinity of Bull Point and Hartland Point to connect those places by telephone with the coastguard line.

4. Connexion of the Tuskar Rock-lighthouses on the Island of Caldy and Lundy with the mainland by means of continuous cables.

5. The Commissioners state that they have found it difficult to determine which rock-lighthouse would be the most suitable station for further testing the system of communication by a non-continuous cable, as recently tried by the Telegraph Construction and Maintenance Company at the Needles, but after careful consideration they are of opinion that the Fastnet would be the best adapted for the purpose, and would prove a valuable station for giving notice of disabled vessels and for communicating storm-warnings; they, therefore, recommend that that lighthouse should be selected for the experiment.

The estimated cost of carrying out the electrical communications herein recommended is as follows:—

I.—LIGHT-VESSELS.

Name.	To be connected by telephone with	Cost of cable and laying.	Cost of land lines.	Total cost.
		£	£	£
Goodwin (North Sand Head).	Broadstairs Coastguard Station.	1,270	55	1,325
Kentish Knock..... ...	Kingsgate C.G.S.	3,531	44	3,575
Shipwash	Aldborough C.G.S.	2,056	44	2,100
Hasborough	Hasborough C.G.S.	2,282	38	2,320
Scarweather	Mumbles C.G,S. or Post Office	2,057	88	2,145

II.—PILE LIGHTHOUSE.

Name.	To be connected by telephone with	Cost of cable and laying.	Cost of land line.	Total cost.
		£	£	£
Gunfleet	Walton-on-Naze C.G.S.	1,414	121	1,535

III.—SHORE LIGHTHOUSES.

Name of lighthouse.	To be connected by telephone with	Estimated cost (approximate).
Start Point.....	Hallsands C.G.S.	£125
Anvil Point	Swanage P.O. or C.G.S.	85
Needles	Totland Bay P.O. or C.G.S.	200
Orfordness	Orfordness P.O. or C.G.S.	85
Girdleness	Torry P.O.	70
Noss Head	Ackergill P.O.	110
Cantick (Orkney)	Longhope P.O.....	160
Mull of Cantyre.....	Admiralty Station	50
Corsewall (Stranraer)	Kirkcolm P.O.	195
Mull of Galloway	Drummore P.O.	215
Douglas Head	South Quay P.O.....	30
Point of Ayre	Admiralty Station, Port Cranstal.	70
Nash (both lighthouses) ...	Llantwit-Major C.G.S.	160
Bull Point	Croyde and Ilfracombe coastguard line.....	—
Hartland Point	Clovelly and Bude coastguard line	—
Minehead (Dungarvan)... ..	Helvick Head Admiralty Station	210
Hook Point (Waterford) ...	Fethard P.O.....	265
Bailey (Howth)	Howth P.O..... ..	85

IV.—LIGHTHOUSES ON ISLANDS OR ISOLATED ROCKS.

Name.	To be connected by telephone with	Cost of cable and laying.	Cost of land lines.	Total cost.
Caldy	Tenby C.G.S. ...	£7,731	£122	£853
Lundy.....	Croyde C.G.S. ...	3,465	149	3,614
Tuskar.....	Rosslare C.G.S..	1,496	226	1,722

V.—ROCK LIGHTHOUSE TO BE CONNECTED WITH NON-CONTINUOUS CABLES.

Name.	To be connected by telephone (combined with Morse Sounder) or by Mirror Galvanometer with	Cost of cable and laying.
Fastnet	Crookhaven	£3,800

It is assumed that the lighthouse authorities will provide the mooring chains, swivels, bow-sheaves, deck-leads for veering cables, and all fittings and appliances for securing the cable drums and windlasses between decks in the case of the light-vessels, and for any builder's work that may be requisite in the case of the lighthouses.

The Commissioners are of opinion that a grant for this purpose should be made out of Imperial funds, and they estimate the amount at £8,000.

They are further of opinion that when connection is established between a light station and a Post office which is not constantly open, an alarm bell should be placed in the room of the telegraphist. They propose to visit other portions of the coast another season, and to take further evidence, especially as regards engineering questions relative to cable communication with rock lighthouses.

The report is signed:—Mount-Edgcumbe (Chairman), Henry L. Mulholland, Edward Birkbeck, F. L. M'Clintock, G. S. Nares, John A. Kempe, R. C. Munro-Ferguson, W. H. Preece, Garnham Roper (Secretary). December 8, 1892.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan.* 20, 1893.

Rapid Transit in New York.—The two most absorbing topics in electrical circles at present are the questions of rapid transit in New York and the policy of the General Electric Company in regard to the incandescent lamp. The Rapid Transit Commissioners, who, it will be remembered, offered the franchise at auction on December 29th, seem still undecided as to their course. It now appears probable that the immediate demand will be met by an extension of the present elevated railway system, using steam, presumably, and that eventually an electric underground route, similar to the Metropolitan in London, will be adopted. One of the propositions which seems to meet with the most favour is to grant additional powers to the Manhattan Elevated Railway Company, enabling it not only to occupy other streets, to broaden its road bed and extend its tracks, but also to extend its structure another story, so as to permit the running of express trains on the upper level while the accommodation trains will use the lower tracks. The interest which electricians have in this question all hinges on the possibility that electricity may be employed as a motive power, whatever plan may be decided upon. But since the present management of the elevated railways has not seemed to favour the substitution of electricity for steam, and as the underground system provides for the employment of electricity, most of those in the profession favoured the latter plan. It is not yet definitely known what course will be taken in regard to this matter, but it seems probable that, for the present at least, we shall have no underground system.

The Incandescent Lamp Question.—The General Electric Company has preserved a discreet silence up to this time in regard to the policy it intends to pursue towards lamp manufacturers; but its recent action by which it obtained an injunction against the Sunbeam, Columbia, and Illinois Incandescent Lamp Companies seems to point strongly to a policy of enforcing legal rights to the utmost. It had been thought by many that while the Company had the undoubted right to put a stop to all manufacture of lamps outside its own establishment, that this course would antagonise public opinion to such an extent as to deter it from going so far. This action has, therefore, come somewhat in the nature of a surprise.

The Westinghouse Lamp.—In the meantime all eyes are turned towards the new Westinghouse lamp, about which so much has been promised and so little has heretofore been made public. While the exact nature of this lamp is not yet publicly known, I am in a position to state more definitely than before just what it will be. The description published in *The Electrician* of November 11, 1892, is, as far as it goes, correct. The shape of the bulb does not differ materially from that of the Edison lamp, except that it is somewhat more slender, and the lower part instead of being closed terminates in a thick bottle-mouth, which is carefully ground to a slightly conical shape; into this fits tightly a ground glass stopper, which extends into the interior of the globe; the leading-in wires are of iron, and to the interior terminals of these are attached the filaments. It is stated that the atmosphere within is one of attenuated nitrogen; but, if this be so, I cannot understand on what grounds the Westinghouse Company makes its claim of increased life and efficiency. To ensure against admission of air after the stopper is inserted a cement is run around, which hermetically seals the junction. This, it is claimed, will soften with heat, and enables the manufacturers to withdraw the stopper and filament at any time, and to renew them without destruction of the bulb. This would seem to introduce a new objection to the lamp, namely, that if this cement would soften by heat it is in danger of being softened in the course of ordinary use of the lamps, which would lead to the destruction of filaments. None of the lamps have yet been placed on the market, nor is it known when they will be.

The Chicago Exhibition.—A new departure in electrical journalism was made by the *Electrical World*, in its issue of January 21st, by the publication of a two-page half-tone illustration of the proposed electrical fountains at the Chicago Exhibition.

CORRESPONDENCE.

USEFUL FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I lately published a rule for finding the heat losses in a copper conductor (dynamo or line) rapidly and approximately as follows:—

(1) With a density of 1,000 amperes per square inch, every 1,000 cubic inches means a loss of 1 H.P. (2) For greater accuracy, add to the horse-power thus obtained one-tenth of its value. (3) For other densities of current, multiply the value thus obtained by the density and divide by 1,000.

Mr. Denny Lane, of Cork, has furnished me with the following equally convenient rule for measuring water-power:—

With a hydraulic motor of 75 per cent. efficiency, it takes 1 acre of water 1 foot deep to give 1 H.P. for 1 hour with 1 foot of fall.

I have long used a somewhat similar formula:—

With 80 per cent. efficiency, 1 cubic metre per second falling 1 metre develops 10 H.P.

These and similar formulæ are of such extreme value in many preliminary engineering calculations that I am tempted to add a few more, and if your correspondents would add to the list something valuable might be attained. I got the following from Lord Kelvin twenty years ago:—

A metre is three feet, three inches and three-eighths, which is easily remembered.

I have long used the following measures of the degree, minute, and second, in terms of a radius = 1. The degree is the only one not very exact, but it is easy to remember the third and fourth figures:—

Rule: After the decimal point, 1° is one nought and a one (exactly 0·0175). 1′ is three noughts and a three (exactly 0·00029). 1″ is five noughts and a five (exactly 0·000004848).

Yours, &c.,
34, Great George-street, Westminster, S.W., GEORGE FORBES.
January 31, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook will be ready on Thursday next. The book will contain more than 1,000 pages, and several new and useful features have been added. The price of the Directory and Handbook will be, as previously, 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

TENDERS INVITED.—The Town Council of Huddersfield invite tenders for a telephone exchange switchboard connecting up the existing departmental lines, and fixing and connecting additional telephone lines. The tenders must be in by February 9th. Further information is given in our advertisement columns.

——— The Directors of the *Yorkshire Post* newspaper have invited during the past week tenders for lighting their premises by electricity.

——— The Directors of the Jesmond and Gosforth Steam Laundry Company (Limited) are inviting tenders for the electric lighting of their large new premises at Gosforth. Particulars can be obtained of Messrs. Oliver and Leeson, 30, Moseley-street, Newcastle-on-Tyne.

——— The Galway Electric Company invite tenders for a new dynamo. Some particulars appear in our advertisement columns, and conditions may be obtained on application to the Company.

Hosted by Google

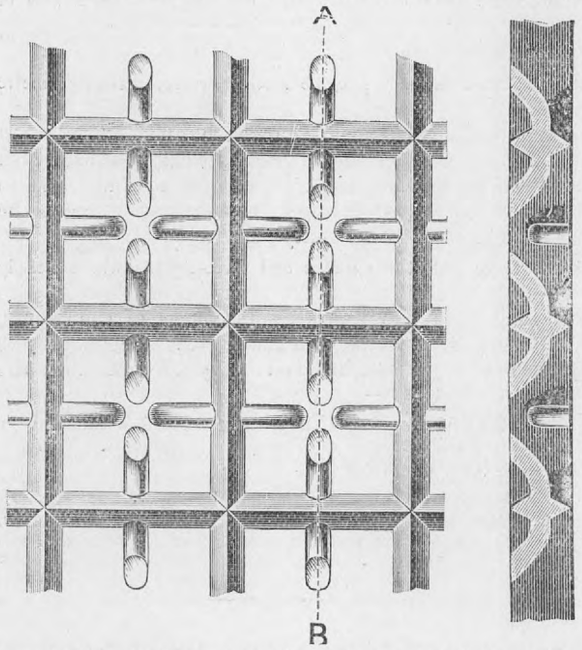
TENDERS INVITED.—The authorities of the Telegraph Department of Florence have recently invited tenders for the supply of 20 tons of galvanised telegraph wire of 5·08mm. diameter, and 100 tons 4·31mm. diameter. The tenders are due to-day (Friday).

PERSONAL.—Mr. G. Stegmann has been appointed sole agent in London and district for the electric light and bell fittings manufactured by Messrs. Lockerbie and Wilkinson, of Birmingham.

GORDON (J. E. H.) AND CO. (LIMITED).—A meeting of this Company was held at the offices, 11, Pall-mall, London, W., on Monday, when it was resolved that the Company be voluntarily wound up, and that Mr. J. D. A. Norris, of Suffolk House, Laurence Pountney-hill, London, E.C., be the liquidator. It will be remembered that an attempt was recently made to convert this concern into a joint-stock company under the title of Gordon and Fell (Limited), but without success.

MESSRS. STONE AND CO.—This firm are forming a branch of electrical engineering at their works at Deptford for the manufacture of a large number of electrical requisites.

THE E.P.S. COMPANY.—This Company are introducing a new grid, called the Patent "Claw" Grid, for use with their negative plates generally, and for both denominations of plates in selected instances. The illustration shows the peculiar construction which enables a large pellet, and consequently a large amount of paste or other active material, to be used in the electrode, while



the conducting surface is largely increased, and the grip for such active material applied by the peculiar "claw" shape ensures that the porous lead or peroxide is firmly held in position, while permitting perfect freedom for expansion or contraction in the mass of the pellets of the active material.

HEAVY HYDRAULIC MACHINERY.—Messrs. J. and W. Weems, Perseverance Iron Works, Johnstone, Scotland, who make a speciality of lead presses, have just constructed and delivered to a well known electric manufacturing firm, for covering electric and telephone cables from ⅛in. to 3in. diameter in continuous lengths, and any desirable thickness of lead, an hydraulic press, 33in. diameter, cylinder and ram; and they have another press in course of construction, nearly finished, 28in. diameter, cylinder and ram, for the same purpose. This firm have supplied special machinery to the principal lead pipe and electric cable manufacturers of the world.

STEAM SAVING APPLIANCES.—The Chadderton Ironworks Company send us their new catalogue of steam saving appliances. Descriptions are given, accompanied by illustrations, of McDougal's patent steam traps, anti-primers, mechanical stokers, a combined steam drier, a water and dirt separator, and other devices manufactured by the Company at their works at Chadderton, near Manchester. The Company claim economy and safety for their specialties.

MESSRS. EDMUNDSONS (LIMITED).—This firm have just issued a list of the principal electric light installations carried out by them in different parts of the country. The list occupies nine pages, and represents about 170 installations, including several steamships.

THE "DEMON" WATER-MOTOR.—Circulars sent us by Mr. Pitman show that this motor, which is of the Pelton or Thirlmere type, is now fitted with a throttle valve governor.

BARRY ISLAND.—At a meeting of the Barry and Cadoxton Local Board on Monday last it was resolved to give the Board's consent to the Barry Company's Bill for the construction of an electric tramway to Barry Island, on condition that the tramway line was moved to the north side of the road instead of being put in the centre.

BOLTON.—The Town Council on Wednesday decided to borrow £40,000 for electric lighting purposes.

BRIGHTON.—A Sub-Committee has been appointed to consider the question of introducing the electric light in the Brighton School of Science and Art.

BRISTOL.—The Electric Lighting Committee of the Town Council at their last meeting decided, as the result of Mr. Preece's report upon the tenders received for supplying distributing mains for the electric lighting installation, to accept that of Messrs. Siemens Brothers and Co. (Limited), at £17,200, subject to certain modifications, bringing the tender down to £16,580. The tenders ranged from about £14,700 to £24,000, there being three tenders lower than that of Messrs. Siemens Brothers and Co. Mr. Preece, however, reported that these latter tenders did not comply with the specifications. It is stated that the rejection of the lowest tender is to be made the subject of discussion at the next meeting of the Council.

COLCHESTER.—At the last meeting of the Town Council a confirmatory resolution was carried that the Council apply to the Board of Trade for a Provisional Order enabling them to produce and supply electricity for public and private purposes within the borough. The Council a month previously had passed the resolution, which, however, it was necessary to confirm in accordance with the rules of the Board of Trade.

COVENTRY.—The subject of introducing the electric light into Coventry has been made the occasion by the *Coventry Times* for an illustrated article on the subject of the application of electricity to various industrial and domestic purposes.

ELECTRIC LIGHT ON THE STAGE.—A feature of the performance at the London Alhambra is a celebrated female dancer "lit by electricity." The effect is described in some of the London papers as "lovely."

GLASGOW.—In connection with the public electric lighting installation, the central station is now reported as practically complete. The engines and boilers are all in position and in working order, the mains in the leading thoroughfares are finished laying, and there is now little more work to be done. Private customers the Corporation expect to be able to supply in the course of the current month.

HERTFORD.—The Mayor and other members of the Lighting Committee of the Town Council have recently visited the works of Messrs. Head and Co. to inspect the plant for the generation of Dowson gas. The Council have a proposal before them for using gas engines worked by Dowson's gas for their electric light installation in the town.

HULL.—At the last meeting of the Electric Lighting Committee of the Corporation, Mr. Holder, the Chairman, announced that the electrical exhibition held in connection with the inauguration of the electric lighting installation had proved a great success, and had been largely attended.

LECTURES.—There has been quite a plethora of popular lectures on elementary electricity lately, and amongst others we note a course of University extension lectures by Mr. H. L. Calender at Plymouth; lectures by Mr. F. G. Baily on "Electric Traction" at Liverpool; by Mr. Barber-Starkey at Shrewsbury; by Mr. J. M. Coone on "Electricity and the Electrical Transmission of Power" at Fowey (Cornwall); by Mr. R. Hammond on "Electric Lighting" at Burton, and by Mr. Brennand at Blackburn; and a course of lectures at the London Institution by Prof. Silvanus Thompson.

LIVERPOOL.—The Parks Committee of the City Council have declined the application of the Liverpool Electric Supply Company (Limited) for permission to lay mains under the grass land in Sefton Park. This is a confirmation of a previous resolution of the Council.

THE LIVERPOOL OVERHEAD RAILWAY.—Lord Salisbury, on the occasion of the opening of the Overhead Railway at Liverpool, will be presented with a novel inkstand. By pressing a button placed on the stand an ingenious device will enable his Lordship to start the train.

LIMEHOUSE.—It has been decided to prepare a statement showing the probable cost of lighting this district by electricity in comparison with the price at present paid for the gas lighting.

MAIDSTONE.—In reference to the electric lighting of Maidstone, Mr. Hawtayne has presented a scheme to the Local Board, in accordance with the resolutions passed in October last. He proposes to erect a supply station at the sewage works with a capacity for 2,000 16 c.p. lamps, and suggests that the supply should be

Hosted by Google

confined to private lighting until such time as the profits from this source justify the extension of the electric light to the public lamps. The idea of utilising water power has, we understand, been abandoned as impracticable. Mr. Hawtayne estimates the outly on plant and extension of mains at £10,450, and recommends that a sum of £16,000 be borrowed in order to obviate the necessity of a second appeal to the Local Government Board. He further recommmends that 8d. per unit be charged. The Lighting Committee of the Local Board are considering the report, and it is proposed to issue a digest to the ratepayers, who will be canvassed as to the support they are prepared to give to the scheme.

North Kensington.—At the last meeting of the Ratepayers' Association the subject of the electric lighting of the district came up for discussion, and it was suggested that representation should be made to the Vestry urging the purchase of the undertaking of the local electric lighting company, in order that the light might be supplied direct by the local authority.

Rottingdean Electric Railway.—No memorial having been presented against the Bill before the Standing Orders Committee for sanctioning an electric railway from Brighton to Rottingdean along the seashore, the Bill passed this stage unopposed. All the necessary statutory deposits have been made.

Runcorn.—The General Purposes Committee of the Board of Commissioners will recommend the Board at the next meeting to instruct Messrs. A. Hall and Co., of Liverpool, to prepare a specification and estimate, and report on the question of the electric lighting of the town.

Scarborough.—We are asked by Mr. A. A. Campbell-Swinton, Managing Director of the Scarborough Electric Supply Company (Limited), and London Representative of Messrs. C. A. Parsons and Co., to announce that the Scarborough Electric Supply Company (Limited), recently incorporated, have decided upon the site for a central station at Salisbury-street, on the west side of the town, near the railway, and building operations will be commenced forthwith. The contract for the engineering plant (including engines, alternators, condensers, boilers, &c.) has been secured by Messrs. C. A. Parsons and Co., of Newcastle-on-Tyne, whose tender (Mr. Swinton adds) was the lowest, and who guarantee their steam turbine alternators at the lowest steam consumption per unit at all loads.——A special meeting of the Town Council was held on Monday last to discuss the minutes of the Sanitary and Lighting Committee, under which power has been given to the Scarborough Electric Light Supply Company (Limited) to increase the pressure of their electric supply from 1,000 to 2,000 volts. The Committee further recommend that 45 per cent. of the capital expenditure of the Company on their undertaking shall be the maximum amount of depreciation permitted. The minutes were confirmed.

Southampton.—At the last meeting of the Town Council a discussion arose in respect to the installation of the electric light at the public offices. The opinion was generally expressed that the immense increase in the shipping of the port which was likely to result from recent arrangements with the large shipping companies should be made the occasion of the Council's agreeing to an extensive installation of the electric light in the borough, and would probably necessitate the building of new public offices. After some considerable discussion it was decided to defer the further consideration of this subject.

Southport.—Last week the first experiment in the public lighting of this town by electricity took place. The landing stage of the North Lake was lit by a 2,000 c.p. Brush arc, and an electric pleasure launch was lit by a 300 c.p. "Midget" and a 50 c.p. incandescent. The experiment was considered satisfactory.

Whitechapel.—At the last meeting of the Board of Works a resolution was moved by Mr. Catmur that it be an instruction of the Streets Committee to consider the question of the electric lighting of the district and to report to the Board. He said the time in which they had now to act was limited, and it would be a misfortune if the matter was allowed to be lost sight of. The motion was adopted.

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The forty-first half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, January 26, 1893, at Winchester House, 50, Old Broad-street, London, Sir John Pender, G.C.M.G., M.P., presiding.

The SECRETARY read the notice convening this meeting, and the minutes of the previous half-yearly ordinary general meeting.

The CHAIRMAN: Before I move the first resolution I will go in detail over some of the accounts, so that you may have impressed on your minds more clearly the results of the working of the last six months. The gross revenue for the half-year under review amounted to £352,391, as against £354,939 in the corresponding period, or a decrease of £2,548. In analysing the message receipts we find decreases in the traffic with certain places, which are almost recouped by the increases in other directions. There is no very considerable fluctuation anywhere, and the amount received from our investments in other companies is practically the same as in the corresponding half-year. The total working expenses for the half-year to September 30, 1892, amounted to £98,797, as against £97,131, or an increase of £1,666, the details of which are as follows:—General expenses in London £9,120, as against £9,412, being a decrease of £292. The working expenses at the stations were £74,486, as against £73,098, an increase of £1,388. Special repairs to buildings at stations are less by £1,461; but, on the other hand, we have written off £1,754 more for depreciation of cable stores, the result being a net increase of £1,666 in the total working expenses.

The expenses attending repairs and renewals of cables, &c., amounted to £37,636, as against £47,047, a decrease of £9,411. It will be seen from abstract C that, in addition to keeping our own cables in a state of efficiency, we have been working for the South African, the West African, and the Brazilian Submarine Telegraph Companies. You are aware that we are all in friendly relation with each other, and we work very much on the co-operative principle. The amounts received from these companies, together with our having to expend less cable on our own repairs, have had the effect of reducing the expenses under this head, which has enabled us, notwithstanding the reduction of £2,548 in our receipts, to carry forward to next half-year £62,847, against £57,509, or an increase of £5,338. I think that that is a very satisfactory statement, and I may mention to you that our ships which have been employed in repairing these cables of other companies have earned us £15,610 this half-year.

As you will have noticed from paragraph 6 of the report, we offered to the holders of the Five per Cent. Debentures, redeemable at par in 1899, the option of exchanging their security for the Four per Cent. Mortgage Debenture Stock of the Company. This offer was responded to by holders of nearly one-half of the Debentures. The Debentures being to bearer, we had to reach the holders through the medium of bankers, brokers, &c., who had presented the last coupons for payment, and in cases where our circulars have not reached the holders we shall be glad to consider the application of any one who is still desirous of effecting the exchange. All particulars as to terms can be obtained at the Company's offices. We have only about £100,000 of these Debentures now to deal with, but, as I have stated, it is rather difficult to reach the holders. The exchange we suggest places the holders of the Mortgage Debenture Stock in a better position than is held by those who have the old bonds. This is standing to-day at something like 7 premium, while the Debenture Stock is at something like 10 premium. To those who want a permanent investment the Four per Cent Perpetual security which we offer is beyond all question a very safe and sound one.

When storms occur we suffer by telegraph communication interruptions, and to-day our connection with Cairo by the land lines there is interrupted through a storm. During the last month we have had many repairs to make, but I am glad to say that every year we gain more experience, which teaches us how to deal with these repairs, and establish our cable system as a sound and reliable property. When I tell you that in the last month we have had ten broken cables to repair, and, as Sir James Anderson reminds me, we have taken out twenty-one faults, you will see it all proves that we have our property very much in hand, and that our ships are generally employed, although it may appear to some of the shareholders that we have a large number of vessels. The system we have adopted of duplicating our cables also makes our system so reliable that the public rarely know if any interruption takes place.

I might, gentlemen, give you all the details of our working in the past half-year, as I have them all before me, but I have given you the principal figures, and I think that they may probably satisfy you that all the details connected with our working are very carefully watched.

Before I ask you to adopt the resolution which I am about to propose, I think I might make a few general remarks. I have just referred to the number of breaks we have had, but the cables are now pretty well in working order, and I hope that before 24 hours are over our land line communications between Cairo and Alexandria will be restored. We have, indeed, at this moment received an announcement that our land lines are now in order to Cairo. The work of repairs has been carried out very quickly. This leads me to refer—but I will do so very briefly indeed—to Egypt, where we have several large stations. We have a very important traffic with that country. I frequently go to Egypt, and I see the working of the English administration there, and I believe there is not a better governed country in the world than Egypt at the present time under English administration. Men of experience are in charge of affairs there, and they are working with unselfish motives. Their only selfishness, indeed, is that they may command the respect and the gratitude of the people of Egypt by their just and wise government. You heard the other day of some little difficulty having arisen there, but it will prove insignificant when dealt with by the men who are representing our interests, and, first of all, Egyptian interests. I have no fear of any trouble arising out of it, and the only reason I refer to it is to tell you we have no politics in this Company. The better Egypt is governed the greater will be the traffic over our telegraph system in connection with that country. We are in very friendly relations with Turkey, and I may say that, however slow the Turks may be in many ways, they are very sharp in making a good bargain, and they take very great care of the money part of their interests. We desire, however, to deal with them in a just and fair way, and although our progress may be slow in connection with that country, it is always going on in favour of our system.

Hosted by Google

Rather a remarkable speech was made the other day by a man who has attained now a European reputation. I mean Mr. Rhodes. He was dealing with what we called some years ago "the Dark Continent," upon which he has thrown light. It is men like Mr. Rhodes who are required in developing a new country. He has shown great ability, great energy, and, I might almost say, adventurous courage, backed with a considerable amount of audacity. He is at the present time endeavouring to open up Africa, as you may have seen in the speech to which I am referring, but which I need not allude to in detail, except in so far as to state that he proposes eventually to carry through Africa on to Cairo a telegraph system, which he thinks some day will enable him to carry telegrams from the Cape to Europe for something like 2s. 6d. against our 9s.; but I should like to show you, on the map we have prepared, the country through which this projected line is to be carried. It is a vast distance from the one point to the other, but Sir James Anderson will explain to you the route by which it is proposed to carry the line and the country through which it is to pass. It is to traverse countries besides those which are under the control of either England or Mr. Rhodes. The Mahdi has a portion of the country, and I think that by the time Mr. Rhodes gets his line to Wady Halfa our arrangements will have enabled us to have paid off our debentures, and we shall then probably have a capital very little more than that which he proposes to use for carrying his telegraph system through Africa. In the meantime, however, everything that he tackles—every territory that he passes through, depends upon his finding gold, and if he finds gold he must of necessity become a feeder to us for a great many years to come. I thought I might mention these facts in order to relieve the minds of any of our shareholders, and to let them see that, instead of the proposed line being a competitor for twenty years to come, it is much more likely—if it goes on—to be a feeding line to us. When, however, it does get to Cairo—and I hope the country will be so developed as to let him get there—we shall be very ready and willing to meet him upon his own ground; and, looking at the greater security which, I may say, exists in a submarine system as against a land line, I think the chances are that we shall not only be able to do the work more accurately and more quickly, but also probably more cheaply than by the proposed line. At the same time I wish him all success in opening up this dark country. It is, however, a very long step from Cape Town to Wady Halfa, and when they get to Wady Halfa they will get into the hands of the Egyptian Telegraph Executive. We may also reckon our speed there at minutes compared with hours by the land lines. As regards competition by it, I feel convinced that there are a very few in this room who will live to see it.

We have just settled, through the Eastern Extension Company—with which this Company is very closely connected—the question of a slight advance in the rate to Australia. As you are aware, the reduction which took place in the rate to these Colonies was very serious—from 9s. 4d. to 4s., the Governments guaranteeing to make up one-half of the loss that might result from the reduction, thus increasing, to some extent, the value of our property by its being backed in this manner. They found, however, that the loss of revenue was not being recouped as rapidly as they had expected, and they therefore asked for an advance of the rate by 9d. We did not think we ought to stand in the way of the wishes of our co-partners in the business, because we took the other half of the guarantee. The alteration in the rate has accordingly been successfully carried out, and, as far as we can see at the present time, we shall, I believe, get back a little more of the former revenue, and thus reduce the loss we sustained by the very large reduction which was at first made in the rate. I think that this pretty much constitutes all that I had proposed to say to you, and I do not think I can wind up my remarks in a better or more encouraging manner than by repeating that we have a very valuable concern, that your property is increasing in value, and that it is likely to be more valuable as time goes on.

I find that there is one matter which I have overlooked. Since I had the pleasure of addressing you on the last occasion, we have made a contract with Her Majesty's Government, in which India is interested, to lay a cable from our system at Zanzibar to Seychelles and to Mauritius. For this we shall get a subsidy for 20 years of £28,000 a year. The new cable will also be an additional feeder to our system. I think this will be acceptable news to you. Altogether, I think we are probably in as strong a position to-day as we have ever been since I have had the pleasure of addressing you.

Before I propose the resolution, I think it will interest you very much if you will allow Sir James Anderson to point out where Mr. Rhodes hopes to carry his land line through Africa. This is a very important matter, and I think that the more our shareholders understand the question, the more they will be pleased with the Company in which they are so much interested.

Sir JAMES ANDERSON (the Managing Director): The line goes at present from Cape Town to Fort Salisbury, and the tariff over that line is 5d., that is, up to Fort Salisbury. Indicating the points on the map, he continued: Then this territory where Tetè is situated is Portuguese, and leave will have to be obtained to cross it. The Portuguese Government, however, have given concessions to other people, so that this proposed telegraph line will not be allowed to be put up there for nothing. After crossing this territory they will come up here to this Lake Country, Lake Nyassa, and further on Lake Tanganyika. On the west it is the Congo sphere of influence, and on the other it is the German sphere; but the Lake itself is neutral. If the line is carried along German territory, they will want to share in the tariff; and if the route is by the Transvaal, they will demand some concession; while if a cable is laid through the Lakes it will be very expensive. When you get to Uganda you are on safe ground, but here you are surrounded by very hostile tribes, and further on the Mahdi will have to be reckoned with, and I do not think that a line will be got there very easily. Then Khartoum, where Gordon was killed, is to be gone through, and so on afterwards into Wady Halfa, where the Egyptian people will have to be dealt with, and they are not likely to carry the traffic for nothing. It will cost in out payments alone something like 3s. 1d. to get from Cape Town to London. It will therefore be seen that if by the proposed new route the rate be 4s., it will leave only 11d. to maintain that portion of the line to be erected all the way from Port Salisbury to Egypt. There is a railway being projected from Mombassa to Uganda—we have a cable at Mombassa; a railway is being built from Delagoa Bay to Pretoria in the Transvaal—our cable connects Delagoa Bay; and a railway is also being made from Beira into the Transvaal. There are therefore three railways in course of construction from the coast into the interior. There is nothing in the history of the world to show that telegraphy or commerce will increase for many years unless it gets to the sea. It is hardly conceivable that anything worth calling commerce will ever grow on this 5,000 odd miles of land line excepting where there is gold, which can hardly be hoped to be found over the whole 5,000 miles. We may therefore look forward to continuing to be the carrying line for commercial traffic from the coast to the interior, for the natives, who do not wear clothes, are not in the habit of sending telegrams.

The CHAIRMAN: I will read what Mr. Rhodes said. "This line to Egypt, provided the Mahdi is 'squared,' will cost £300,000 to £400,000, and we have lying to the east and west of the coast (that is our system) cables which cost over £3,000,000. We are now charged 9s. 6d. a word for our communications, but when we can get to Egypt by the telegraph I am referring to, we shall be able to do it for 1s. 7d. from Egypt to England, or, in all, about 2s. 6d. against 9s. 6d. a word." That is the statement, but I think we have shown you pretty clearly that he has difficult ground to go over, and that for a long period of his working he must be feeding us all the time, and moreover, that our finances are so arranged in regard to our Cape cables that at the end of the 20 year's contract we shall have paid off our debentures, and have our cables for practically a very small sum. Therefore, if it comes to a question of competition, I am quite sure that we shall be able to do the work as cheaply as Mr. Rhodes; but, as I have said already, that will not occur in our lives. There are some young people present, and Africa may be developed in their time, but it will not be developed to the extent Mr. Rhodes expects in his time or ours. The resolution that I have to propose is as follows:—

"*That the report and accounts of the Directors to September 30, 1892, submitted to this meeting, be and the same are hereby received and adopted.*"

The VICE-CHAIRMAN (Lord Tweeddale): I beg to second the resolution.

The CHAIRMAN: If any gentleman has any question to ask or any remark to make I shall be very glad to hear it before I put the motion. If no one has anything to say I will put it, and those who are in favour of it will please hold up their hands. To the contrary. Carried unanimously. I feel, in a sense, a little disappointed, for I think this is the first time that I have ever addressed you without there being some gentleman who was desirous of saying a word, and I am always ready to answer any questions. The next resolution is—

"*That George Garden Nicol, Esq., who now retires, be and he is hereby re-elected a Director of the Company.*"

The MANAGING DIRECTOR: I have much pleasure in seconding the motion.

The CHAIRMAN: I may tell you that Mr. Nicol is one of our oldest Directors, and has, in fact, been associated with the Company from its inception. He then put the resolution in the usual way, and it was carried unanimously.

Mr. NICOL: Gentlemen, I thank you for the honour you have done me.

The CHAIRMAN: The next resolution is as follows:—

"*That John Denison Pender, Esq., who now retires, be and he is hereby re-elected a Director of the Company.*"

The VICE-CHAIRMAN: I beg to second the resolution.

The CHAIRMAN: As you are aware, Mr. John Denison Pender is my son. He has been trained to this work, and I hope, as time goes on, he will prove to be a better man than his father in carrying it on. He then put the motion in the usual way, and it was carried unanimously.

Mr. PENDER: I beg to thank you, gentlemen.

The CHAIRMAN: The next motion is to come from the body of the meeting.

Mr. COOPER: I beg to propose:—

"*That Mr. Henry Dever and Messrs. Welton Jones and Co., both of whom now retire, be and they are hereby re-elected auditors of the Company for the current year, at a remuneration of £100 each.*"

Mr. C. BURT: I have very much pleasure in seconding the motion. These gentlemen are well-known as accountants in the City of London, and no better men could be found for this work.

The CHAIRMAN put the motion, and it was carried unanimously. Continuing, he said: I think it is right at this time, when so much is being said about companies and the way they keep their accounts, to tell you that from the time we formed this Company we thought it a wise and prudent thing, in the interests of the shareholders, and also for the protection of the Directors, that we should have first-rate competent accountants, who would be responsible for the accounts as between the Company and the shareholders, and I can say with great confidence that that duty is faithfully and well performed by our present auditors. I think that closes the whole of the proceedings of this meeting.

Mr. H. T. BURGESS: I beg to propose that the best thanks of this meeting be given to our excellent Chairman and to the Directors of this Company. I think that if you were to go through the whole of the City of London you would not find such an able body as we have to manage this business. I think they deserve the very best thanks of this meeting, and we wish them very many happy new years.

Mr. WOOD: I second the motion.

The resolution was carried unanimously.

Hosted by Google

The CHAIRMAN: On behalf of my colleagues and myself I return you our very best thanks. This is not the first occasion by very many times that you have paid us a similar compliment, and I can only say that we try, as far as lies in our power, by carefully looking after your interests, to retain and to increase your confidence in us.

The proceedings then terminated.

Direct United States Cable Company, Limited.

The thirty-first ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, London, on Friday, January 27, 1893, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. T. Finnis) read the notice calling the meeting, and the minutes of the last ordinary general meeting, which were approved by the present meeting, and signed by the Chairman as correct. The Directors' report was taken as read.

The CHAIRMAN: Before asking you to approve the report, I shall as usual go over the details of the working of the past six months. The revenue for the half-year, after deducting outpayments, amounted to £43,629, and the working and other expenses, including income tax and depreciation of spare cable, but exclusive of cost of cable repairs, to £18,982, leaving a balance of £24,647 as the net profit of the half-year, making, with £3,730 brought forward from the previous half-year, a total of £28,377, which has been appropriated as follows:—Interim dividend of 3s. 6d. per share for the quarter to September 30th, £10,624; interim dividend of 3s. 6d. per share for the quarter to December 31st, £10,624; transferred to reserve fund, £4,000; balance carried forward £3,129, making a total of £28,377. The revenue, as compared with that of the corresponding period of the previous year, shows a reduction of £1,773; but under all the circumstances, and looking to the depression existing in many departments of trade, we have, I think, good reason to be satisfied with this result. The expenses in London show scarcely any variation in the items, and on the whole they are within £5 of the same amount as in the corresponding period of 1891. The expenses at stations, on the other hand, show as follows:—Increases of £122 in salaries, £100 in maintenance, £95 in petties, £126 in rent, fuel, and light, and £172 in repairs and renewals, with a reduction of £55 in printing and stationery. The above increases are mostly due to the new receiving station at 39, Mark-lane, and, with the further addition of £319 for Continental agencies, an item which did not appear in the accounts for 1891, the increase of £868 in the stations expenses, as a whole, is accounted for. In the further expenditure, a saving of £158 is shown in Directors' fees. The expenditure in the aggregate exhibits an apparent increase of £1,309, but it must be pointed out that this includes £1,000 written off the acquisition of Patent Rights account, an item that did not appear in the accounts for the corresponding period, and the real increase is therefore £309 only. Turning to the reserve fund, it will be seen that that account is credited with £4,271 for interest on the investments, £3,611 for profit on security realised, and with £4,000 transferred from the revenue account, while, on the other hand, £6,301 is debited for cost of repairs, leaving the balance standing at the increased figure of £260,298. The investments now stand at a cost of £234,152, but their present market value is nearly £260,000. Now, gentlemen, that is not an unsatisfactory state of things to put before you, and I think at a time like the present, when companies are being brought very much before the public, and when they are being very carefully looked into, I might give you some little idea of the position of our Company in comparison with the other telegraph Companies working in the same seas—namely, the Anglo-American, the Western Union, and the Commercial Companies. At the present moment, if you take into account the dividends and the value of the properties in the market, our Company is paying probably the highest rate of interest of any of the others that I have mentioned. We pay practically 5⅞ per cent., against the Anglo-American Company's 5 per cent., against the Western Union's 5½ per cent., and against the Commercial Company's 3 15-16 per cent. The Commercial Company occupies the peculiar position of its stock being at a large premium, while those of the other Companies are at a very large discount; but the people who are our constituents—the shareholders generally in this Company—all stand with their property at a reduced rate. In other words, we may call the present value of our cable something like £460,000, as against a much higher figure in the case of the other cables. For instance, each of the cables of the Anglo-American Company stands at an average of £712,500 against, as I have said, £460,000 in the case of this Company. Altogether, therefore, we stand in the position of having written our cable down to a lower price, and at that lower price the dividend that is being paid to-day is practically, or it ought to be, about 6 per cent., but really we are paying you 5⅞ per cent. Altogether the figures which I have given you show that, taking our concern from every point of view—as to value, as to the dividend paid, and as to reserve fund—we stand above any of the submarine telegraph companies working to America. That may be so far satisfactory to you, and it is always satisfactory to be informed from time to time respecting the real value of one's property. Before going from that point I may mention that we are watching very closely the working of the system. We are carrying our traffic speedily and correctly. We have also just opened a new office in Mark-lane, and if you were passing there and were to look inside, you would see that it is an office which apparently belongs to a thriving concern. You will observe from the newspapers from time to time that our work is recognised as not being inferior to that of any other Company, and, perhaps, in some respects, it is better. Altogether we have no reason, although we are a single-cable Company, to feel other than pleased at the position we occupy among the Atlantic Cable Companies; and one of the advantages that we have—of course, we have to pay more or less for it—is that if anything were to occur to any of our lines, we have 12 months in which to repair them before we can lose any portion of our revenue. The other Companies guarantee us, as we more or less guarantee them, against breaks occurring. Our cable is getting old, as you know, but at the same time, when we have effected repairs—and we have had rather more repairs than we like—we have materially strengthened our cable, so that at the present time, although it is about 18 years old, I believe that our cable, our main cable, is very little inferior, seeing what we have done to it, to what it was when it was originally laid down—very little, if anything, inferior. That is also a comfort to you looking to the future. I think, therefore, that I may congratulate you and ourselves upon occupying the position which we do fairly and respectably, and, upon the whole, profitably. I should like to see bigger dividends, but when you look at the depression which has prevailed one way and another; when you look at the fact that there are in the Atlantic now 10 cables and when you remember the further fact that science has enabled us to duplex those cables and do the work of some 20 cables, the wonder is that we occupy as profitable a position as we do at the present time. It takes a long time for commerce to grow up to the requirements of our cables, but we have done an enormous amount of good to commercial people generally by giving them facilities for turning over their capital so much oftener than they could have done by the postal system. I believe that the growth of telegraph enterprise is certain. Had it not been that these cables were duplexed as regards their carrying power, we should probably have received a little more than we are getting to-day, but we have this advantage—that as the increase in the traffic goes on—and growth there is—we shall be for a long period of time able to meet it, and we are not, we think, in any danger now of having new cables laid to compete with those already existing, which are so largely ahead of the requirements of the commercial world. Before I leave the subject altogether of our telegraph system I think I may refer to a death that has occurred lately. On the last occasion when I addressed you I had the deep regret of announcing the death of two of our Directors, as well as the death of a man whose name is associated with submarine telegraphy from its inception—I refer to Mr. Cyrus Field, the two Directors we lost being Admiral Mayne and Mr. Ford. To-day I have to announce the death of a man who has been very conspicuous indeed in connection with submarine telegraphy—I allude to Mr. Jay Gould. Probably no man who ever lived did so much for himself in such a period. Whether he benefited submarine telegraphy or not I am not going to say, but this I may tell you, that he was the largest holder of telegraph shares in the world, and as such I recognise him; and in referring to his death I will only say this: that if he did not do a great deal for us in one way he did in another by carrying on an extended system. I believe there is no system more extended in the world than the system of land telegraphy in America at the present moment. Therefore, his name will be associated with the progress of telegraphy, and whenever its history generally is written I do not think it will be possible to leave his name altogether out of record. I think I have now exhausted all the remarks that I have to make. We have opened another station, as I have said, and we are putting our people at Ballinskelligs into more comfortable quarters. We have also still on hand the lawsuit which I referred to on the last occasion, when I gave you all, I think, good advice, in telling you that if you ever quarrel with a Frenchman never go to law with him. That is my experience. When this suit is to be finished I cannot tell you, but I do not think it is doing us much harm, although it has done us no good. With these remarks I beg to move:—

"*That the report of the Directors, dated January 13, 1893, together with the statement of accounts to December 31, 1892, annexed thereto, be and the same are hereby received and adopted.*"

Mr. E. M. UNDERDOWN, Q.C., seconded the motion.

The CHAIRMAN then invited discussion, but no shareholder rising to address the meeting, he put the resolution, and declared it carried unanimously, adding that that closed the business.

Mr. HANCOCK proposed a vote of thanks to the Chairman, Directors, and officials of the Company. He came to the conclusion long ago, and had no doubt whatever on the point, that this Company's was the best of the whole of the Atlantic cables. In manufacturing it Messrs. Siemens strove to give the Company a first-class cable, and he thought they had succeeded. It was very evident—and this was an important point—that those who had the manufacture of the cable and the sending of the messages performed their duties very skilfully, as was shown by the results attained. Their property was a growing one, and the value of the shares was being more and more appreciated by the public. It was very satisfactory to them to see that that was the case, and altogether he felt that the shareholders must feel unbounded confidence in the Directors for their watchfulness in protecting the interests of the Company.

Mr. JOHN NEWTON seconded the motion, and said he trusted that the Board would not assume, from the sparse attendance on that occasion, that the shareholders felt any less interest in the proceedings of the Company. Probably the circumstance that so few were present was owing to the fact that the Directors now circulated an excellent report of the proceedings among the shareholders. He was surprised that their shares did not stand better in the market, for they were an excellent investment, and the position of the Company was most satisfactory.

The resolution was carried unanimously.

The CHAIRMAN, in reply, said: On behalf of my colleagues and myself, I thank you very warmly indeed. With regard to the French suit, I have often heard it said that one reason why an Englishman can never get satisfactory settlement of an action in France is that the French people do not like the money to leave the country; and possibly that is the case in connection with the suit between the Anglo-American Company and the Paris and New York Company. As to the French Company having a very large surplus of capital at command, I am afraid that this is not the case, and they are paying no dividend at all. The consequence is that,

Hosted by Google

if our people gain the suit, they might not obtain much material advantage by their success; but, at all events, we have so far gained the day, and we will live in hope of some benefit accruing to us, hereafter in connection with this matter. With reference to Mr. Newton's remarks they were quite true, and I have very often found that if companies are prosperous, there are very few shareholders at the meetings, while if they are in a bad state the attendance is very considerable. Our submarine telegraph companies have now got such a firm hold of the confidence of the public, that our Four per Cent. Debentures—I speak of the Eastern Company over whose meeting I presided yesterday, the South African Company, and the Eastern Extension Company—are quoted to-day at from 10 to 12 premium. That is a very remarkable evidence of the confidence which the public have in these undertakings now. The submarine telegraph system is growing and becoming stronger as it grows, and I am all the more glad to say this now when I see Mr. Newton present. He has been with us almost from the very beginning, and he used to criticise us—in fact, he used to come to our meetings to curse, while now he attends them to bless. That is a great compliment to the Companies, but I think it is also an indication of Mr. Newton's good sense and judgment.

A SHAREHOLDER inquired the proportions of the traffic originating in America and at this end of the system.

The CHAIRMAN: I will answer you in a sort of half-and-half way; I will not do so in a direct manner. As a rule, younger people have greater energy than old people, and we find that illustrated both by the Australian and the American people. Everyone in America wants to be a "boss." In England everyone wants more to keep what he has got, and is not very ready to run risks to get more. But it is good for our Companies that risks should be run, because they involve telegraphing. I might, therefore, say offhand that probably more of the telegraphing comes from our colonies and from America than goes from this country. That will suffice to give you a rough idea of the position.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held at Winchester House, Old Broad-street, on the 27th ult., the Most Hon. the Marquis of Tweeddale presiding.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last meeting, these being confirmed and signed as being correctly drawn up.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, the half-year, which came to a close on December 31st, has proved a disappointing one so far as our traffic receipts are concerned. The first half of the year showed an increase of £10,035; the last half a decrease of £4,669. The explanation is that business has been dull, and the dulness is reflected in our traffic receipts. Competition has been as keen as ever, and more costly to all interested in Atlantic Cable Companies. We have no reason to suppose that the pool companies have in consequence suffered more in proportion than their rivals. Probably the contrary would prove to be nearer the truth. Happily our repairing ship "Minia" has benefited the revenue account to the extent of £3,000 earned in repairing the Direct United States and Western Union Company's cables. Our expenses are very considerably lower; the items of working and law expenses are less by £1,368, and repairs of cables £4,123. Allowing £613 loss incurred by the fire in Newfoundland, there is a net decrease in expenses of £4,878. Then you will note that we have credited the renewal fund with a sum of £2,021, being the amount of unclaimed dividends up to 1882—ten years ago. This sum is unquestionably the property of the Company, and we believe that the proprietary will approve of its being merged in the renewal account. It is not probable that, after so great a lapse of time, many dividend warrants will be presented for payment. Whenever they are presented they will be paid. The renewal fund had only for the first time reached a figure in excess of that which your Directors have always held should be set aside for renewals of cables, viz., £1,000,000. They decided, after due consideration, to carry the amount—viz., £1,619—to the revenue account, or, in other words, to make that amount available for dividend, thus enabling your Directors to recommend a dividend at the rate of 30s. per cent., as against 28s. 6d. in 1891—making a total distribution for the year of £2. 15s. per cent. on the ordinary stock. This may appear to some a very poor dividend; but it must not be overlooked that a large portion of the seven millions of the Company's capital is water—not less than half—on which the present dividend would pay at the rate of 5½ per cent.—not a bad return on the capital of a Company which has a reserve worth considerably more than a million. The report informs you that our cables are in good working order and condition. I may add that I believe our system to be in a very high state of efficiency, reflecting credit on our *employés* both ashore and afloat, upon whose energy and skill and accuracy the success of our Company so much depends. The appeal in the French Courts makes no progress, and is not likely to make any so long as M. Barboux, our counsel, and M. Waldeck Rousseau, counsel of the French Telegraph Company, are occupied in the Panama litigation. I do not think that the report or accounts call for any very lengthened remarks on my part. I have only to say, in addition, that we have begun the year tolerably well. The increases recorded up to the present time are satisfactory, and if these be continued during the year, which is not impossible, we may look forward to a better return than we have been able to submit to you to-day. I have now to move:—

"*That the report of the Directors and accompanying statement of accounts to December 31, 1892, submitted to this meeting be, and the same are hereby received and adopted, and that the following dividends as recommended by the Board be now declared and paid, less income-tax, that is to say:—*

"*1.—A final dividend of 17s. 6d. per cent. upon the Ordinary Consolidated Stock for the year ended December 31, 1892, making (with £1 17s. 6d. per cent. interim dividends already declared and paid by the Board by way of dividends on account) a total dividend for the said year of £2. 15s. per cent. on the said Stock.*

"*2.—A final dividend of £1. 15s. per cent. upon the Preferred Ordinary Stock for the year ended December 31, 1892, making (with £3. 15s. per cent. interim dividends already declared and paid by the Board by way of dividends on account) a total dividend for the said year of £5. 10s. per cent. on the said Stock.*"

The DEPUTY-CHAIRMAN (Mr. Francis A. Bevan) seconded the motion.

Mr. DAVIS desired to know when the French appeal case would be settled. It had been said from time to time that the case was going on satisfactorily, but surely the time had now arrived when some definite information should be obtained as to how long it was to go on. He would suggest that if it was a bad debt they should mark it off; but if it was a good one, it should be put to their credit.

Mr. EDWARD CLARK, who said that he had been a shareholder for a great many years, although he had never attended one of the Company's meetings before, wished to ascertain how much inward and how much outward traffic there was. He was in a position to say that their rival Company—the Commercial—was making great strides in order to get the business on this side, and he wished to know whether the Directors were taking steps with a view to meet such a possibility. One suggestion I would wish to make, namely, that if there were any vacancies on the Board, he hoped that they would be filled up by practical, business men, who were in touch with the telegraphing world.

Mr. CHESTER said that for several years they had had the question of the Deferred shareholders and their interest in the Company brought before the shareholders. Time after time they have been told that when the reserve fund reached a million sterling the Deferred shareholders would have the benefit of any surplus. Their investments, which placed a great responsibility on the Board if they fell in value, were put down at a million sterling in the revenue account, and were worth £990,000, and he wished the Chairman to give them the assurance that the interest from the renewal fund, as well as that from their investments, should henceforward be credited to the dividend fund.

Mr. GARNER asked whether they could bring about the conversion of the Ordinary and Deferred stock if it were desirable.

A SHAREHOLDER agreed with Mr. Chester that the interest on the renewal fund ought to be divided amongst the shareholders. He thought that the Chairman at previous meetings was disposed to do so.

Sir JOHN SWINBURNE said that he happened to be in the unfortunate position of having invested in the stock twenty-nine years ago something like £1,300 or £1,400, which was now written down to £800. What he now received was about 2½ per cent. on the latter amount, which was about 1½ or 1¼ on the original investment, and he would urge the Board to divide as much as possible of the revenue they derived from the renewal or reserve funds, which for all practical purposes amounted to the same thing.

Mr. GRIFFITH, referring to the statement of the last speaker that the stock of the Company had been very much written down, said that he was afraid that the Company had suffered greatly from the amalgamation with other companies at high prices. He was afraid that they must admit that the stock was considerably "watered," but on the other hand they had the good fortune to have accumulated a reserve fund of upwards of a million sterling, taking it at its market value. He was under the impression that in times past the Directors were willing to be content with a reserve fund reaching the large figure of a million sterling; and, considering how long-suffering and patient the Deferred shareholders had been, he hoped that the Directors would take a little pity upon them, and divide among them the interest on that very large fund. Referring to the French appeal case, he was glad, on looking at the "Stock Exchange Year Book," to find that the Court of Appeal decided in their favour, and that it was only the question of damages which was deferred. Perhaps the Chairman would give them some information as to how much they might expect in the way of damages.

Mr. NEWTON advocated what his friend Mr. Clark had done—that in future the interest on the renewal fund should be placed to the revenue account.

The CHAIRMAN said he was very glad to see so large an attendance of shareholders, a circumstance which he ascribed in a great measure to the action the Board had taken with regard to the renewal fund. It seemed to have had the effect of whetting the appetite of the shareholders. As to their French case, it was still in the hands of the judges. Mr. Clark had asked a question as to the outward and inward traffic, but it was not desirable or expedient that such information should be given as to the vacancies on the Board, the Directors would be glad to take Mr. Clark's hint whenever a vacancy did occur, to recommend a business man. He did not know whether Mr. Clark meant to suggest that the gentlemen on the Board now were not business men. When they had such men looking after their interests as Mr. Bevan, Sir James Anderson—who had a large connection with the telegraphic world—Mr. Samuel Barber, Mr. Charles Burt, Sir Albert Cappel—who had a large Indian connection—and Mr. W. S. Cunard, he hoped it might be considered that they were a fairly representative body of business men. As to the renewal fund the question resolved itself into this, what was to be the lowest figure at which they could allow the renewal fund to stand? The Directors had arrived at the conclusion, not to day nor yesterday (for many years the subject had been considered

Hosted by Google

and threshed out), that they could not afford to do without one million sterling as their renewal fund. That was their deliberate judgment, which was really the crux of the whole question. Some gentleman had described it as a very large fund. It was by no means so, having regard to the fact that they had four cables, and that one of them was very old, and might at any time involve large expenditure on its renewal. The Direct United States Company had at least as large a fund in proportion to its capital. As to the responsibilities of Directors, in respect of investments, it was their duty to invest their money in the best possible securities, and he thought that if they did so properly, no other responsibility was likely to arise. Their stock had not been written down, as Sir John Swinburne seemed to think.

Mr. BURT said that Sir John Swinburne referred to the old Atlantic Telegraph Company's stock, which was taken over by the Anglo-American Company at a reduced figure.

The CHAIRMAN, continuing, remarked that from what he had said they would see that it was impossible for the Directors to give any pledge to invariably every year credit the revenue account with the interest on the renewal fund. All that they promised to do was what they had always promised, namely, that when the renewal fund exceeded one million pounds they would take into consideration the question of applying the excess to dividend.

The SECRETARY, in reply to Mr. Garner, said that the ordinary stock could be converted into Preferred and Deferred Stock at any moment during the three months, January, February, and March of each year, at the option of stockholders. He further added that the cash (£45,000) not yet invested, forming part of the Renewal Fund, was not at present available for investment, being employed in the general business. There were amounts owing by and to the Company which had to be settled, and which required an amount of floating cash.

The CHAIRMAN said that all the money which they had available for investment was at once invested.

The resolution was then put to the meeting, and carried unanimously.

The CHAIRMAN next moved :

"*That Sir James Anderson, who retires by rotation at this meeting, be, and he is hereby, re-elected a Director of this Company.*"

Mr. BEVAN seconded the motion, which was carried *nem. con.*

Sir JAMES ANDERSON having expressed his acknowledgment,

The CHAIRMAN moved :—

"*That Mr. W. S. Cunard, who retires by rotation at this meeting, be, and he is hereby, re-elected a Director of this Company.*"

Mr. BEVAN seconded the motion, which was carried unanimously.

Mr. JOHN NEWTON moved :

"*That Mr. Joshua Dean and Mr. John Gane, F.C.A., be, and they are hereby, re-appointed Auditors of the Company for the current year, and that their remuneration be £100 each.*"

Mr. GRIFFITH seconded the motion, which was carried unanimously.

Sir JOHN SWINBURNE proposed and Mr. GRIFFITH seconded a vote of thanks to the Chairman and Directors for their able conduct of the Company's business during the past year.

The CHAIRMAN having briefly returned thanks,

The proceedings terminated.

City and South London Railway Company.

The seventeenth half-yearly ordinary general meeting of this Company was held on Wednesday last at Winchester House, Old Broad-street, Mr. C. G. Mott presiding.

The SECRETARY (Mr. W. F. Knight) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN : Gentlemen, it now becomes my duty to move :—

"*That the report of the Directors and accounts presented to the meeting be received and adopted.*"

Although we should have been glad if we had had a larger accession of traffic during the past half-year, and been able to pay a better dividend than we are able to do, still, on the whole, I think you will agree with me that our report shows a very decided and substantial progress, and that the condition of the line altogether is satisfactory. During the past half-year we have carried, including the season ticket holders, 600,000 more passengers over those of the same period last year, and we have carried since the opening of the line up to the present time more than 12,000,000 passengers, and I am thankful to say we have done so safely and without any accident of any consequence whatever. You know well that, during the early stages of this line, I had half-year after half-year to deplore that there should have been so many defects in our working, and that our traffic suffered in consequence. It is very satisfactory to think that during the last half-year we have had practically no stoppage of that kind whatever. I do not think that there is any railway that could give better results in point of working for punctuality, regularity, and convenience than this line ; and, considering that it is the first electric railway, and that we have had only two years' working, this augurs well for the future of similar undertakings. Beyond the fact that we have done, as I think, fairly well for the half-year, the Company has improved its position financially very considerably. A year ago we had a large amount of Lloyd's B bonds and a considerable amount of debts which pressed heavily on the minds of the Chairman and the Board, but I am happy to say that to-day these amounts, since the accounts were published, have been very largely reduced, and that we have been able to pay off every debt that we owed, and, furthermore, that we have funds in hand sufficient to pay off every one of the terminable debentures that become due within the next nine months. Therefore, our position financially is an exceedingly strong one. Turning to capital account you will see that during the past half-year we have issued preference shares to the amount of £18,500, and we have expended on capital account out of that £4,436 ; we have paid off £6,000 of debentures, and we have reduced our debts by £8,000, which accounts for the £18,000 raised. Since these accounts were made up, we have issued a further amount of preference stock, and as far as the Board is concerned we have issued all that we intend to issue at present. As regards the question of the debentures, in order to give our existing debenture holders every reasonable opportunity of improving their position we offered to them that, if they would convert their present debentures into the permanent Four per Cent. Stock they would be allowed to do so at par ; or if they preferred it they would receive in exchange our Five per Cent. Preference Stock, also at par. About one-fourth of our debenture debt has been so converted, the other three-fourths have not been, and will have to be paid off or dealt with as circumstances may suggest. Those who took advantage of the offer we made were very wise I think. Our debenture capital has risen to a considerable premium, and I have no doubt it will go very much higher than it at present stands at, because it is as secure a stock as you could possibly have. Inasmuch as we shall be able to issue debenture stock from time to time at a premium, we shall be able so far to reduce the amount of our debenture interest, and I anticipate that in future we shall be able to make each half-year a considerable saving in interest. Coming to the revenue, which is the most interesting part of an undertaking of this kind, our receipts from passengers during the half-year have been £21,462, against £19,550 in the corresponding period of 1891. Season tickets have brought us in £540, against £249 in 1891, and our parcels and other small receipts have brought in £15, against £5 in the same year. Our parcel traffic is slowly augmenting, and we have under consideration whether we cannot considerably develop it. Our transfer fees are £9, against £4 last year, while our rents are £562 against £435, whilst our sundry receipts are £400 against nothing last year, making a total of £22,652, or an increase of £2,409 for the half-year. You know that in most railways an increased traffic does not mean a net increase in profit, because it is absorbed in working expenses. I am happy to say that it is not so with us. Our maintenance has been decreased £101 ; our locomotive expenditure has increased £148, and our carriage repairs have increased £51. Our traffic expenses have decreased £317, our general expenses have risen £110, our law charges £8, our rates and taxes remain the same as before. The result is that there is a net decrease of £127 against that of the corresponding period last year. The result of the half-year's working is that we have made a profit of £7,262, against £4,727 in the corresponding period of 1891. This added to the balance brought forward makes a balance of £8,304, of which the debenture interest absorbs £4,259, leaving £4,045 available for dividend. This will pay 5 per cent. on the preference shares, and $\frac{5}{8}$ per cent. on the ordinary, carrying forward a balance of £822 to the next account, which is the same as we carried forward last year. I am happy to say that, so far as our experience of the present half-year is concerned, we have shown a very satisfactory increase of traffic. It has averaged an advance of £150 a week since January 1st, and if this continues I hope that at the next meeting we shall have a much more satisfactory return than we have at present. You may be interested in seeing how far this electric traction promises to be successfully and economically worked. We have had four complete half-years in which to form a comparison. In the first half-year all the expenses which are commonly comprised under the head of locomotive charges in a steam railway were 9d. per train mile ; in the next half-year these were reduced to 7·9d. ; in the following six months to 7·7d. ; and in this half-year to 7·1d. In order to compare favourably with the expenses of large railways, such as the Midland, Great Western, and the London and North-Western, you must recollect that in their case they take the price of coal at the pit's mouth, charging no carriage upon it, whereas we have to pay carriage from the mine to London, besides a heavy charge for conveying the coal into our depôt ; so that if we reduced our price of coal to what is paid for it at the pit's mouth, our expense would be only 5¾d. per train mile. That I think is a satisfortory thing, seeing that in an ordinary steam railway it is very rarely below 9d. We have run during the half-year about 70,000 trains, and including our season ticket holders we have averaged 48 passengers in each train. The first half-year we averaged 45, the second 46, and the last 48 passengers per train. The total percentage for working expenses during the first half-year was 79 per cent. of the receipts, for the second 76 per cent., for the third 70 per cent., and for this half-year 67·9 per cent., so that the expenditure is coming down very steadily and satisfactorily. If you make comparisons in this connection with other railways, you must take out of our expenses what we have to pay for lifts, and if you deduct that item you will find that the working expenses are only 59¼ per cent. of the receipts ; and I hope as our traffic increases that you will see a diminution of that figure. During the past half-year, during our busy time we have been running an additional train service, which has involved us in an extra 1,000 miles a week. Therefore, our mileage has gone up considerably. Of course you will see that we have been giving more accommodation during the busy times of the day, and the result has been that our receipts per train mile have been only 2s. 0½d., against 2s. 1d. during the previous half-year, or ½d. less. Our expenses per train mile, on the other hand, were in the first half-year 1s. 9½d., then 1s. 6¼d. ; in the second half-year they were 1s. 7¼d., and last half-year they were 1s. 5¼d., so that they are coming down very satisfactorily. You gave us authority some time since to convert our ordinary share capital into stock. We have availed ourselves of those powers, and have converted the 60,000 shares which existed into £600,000 of Consolidated Stock. The conversion has been largely carried out already. There remains, however, some 3,000 shares, and we propose to call a special meeting to convert these also into Consolidated Stock, so that the whole of the share capital will in

Hosted by Google

future come under that denomination. I want now to call your attention to the position of our Parliamentary business. You will remember that the Bill of last Session, in consequence of the dissolution of Parliament, could not be gone on with by the Committee, and it was carried over with several other special Bills to the present Parliament, and it will be taken up at the point at which it was left last Session, and I hope and trust that we shall be able to get it carried through as we desire. As to our Clapham extension, we propose to carry that out so as to give us relief in the way of sidings, &c., but it would have been a useless and fruitless expenditure to have completed that line by the present time. Therefore we thought it better to leave the Bill in abeyance, and postpone any action in the matter, and we have lodged a small Bill to give us an extension of time in order that we may have ample opportunity to consider matters. The sidings at Stockwell are very much wanted, and we have contracted for carrying them out; but, unfortunately, we have been met with a good deal of opposition at the hands of the Vestry in the neighbourhood. We have chosen the very best position for them, but the Vestry have not shown any desire to encourage us or their own constituents. We are willing to give them the accommodation, and I think we ought to receive every encouragement from them. However, we have the authority of an Act of Parliament and we must exercise it, and we propose to commence those works.

Mr. HANBURY seconded the resolution.

Mr. DRAKE congratulated the Directors and shareholders upon the favourable position of the Company as disclosed by the data given by the Chairman. He had previously criticised the Board severely, but he had done so in ignorance of the real facts. Theirs was the pioneer electric railway in London, and he was sure that if things went on as they had done for the last twelve months that they had a prosperous future before them. He wished to compliment the staff for the able way in which they had performed their various duties during the past six months.

Mr. MIDDLETON said that he was glad to see that since the report was issued there had been an increase of traffic on the Company's line. He must point out that whilst they had increased their train mileage they had decreased their train mileage receipts. Last year they were 2s. 2½d. per train mile, while this half-year they were 2s. 1½d. This meant £1,700 which they gave to the public. Before reducing the fares, some consideration should be shown for the ordinary shareholders. Their railway had been worked for the last year without any appreciable delay or inconvenience, and he thought that it was only right that those who were in charge of their machinery at their depôts should receive their meed of praise for the efficient manner in which they had carried out their duties. He thought, however, that there was room for economy all round. The cost of administration was out of proportion to the capital; and he would like to ask the Directors to forego part of their fees until the dividend reached 2 or 3 per cent. The whole of the energies of the Board and staff ought to be directed to the perfecting of their line as it at present existed, and not to the extending of their wings to Islington or anywhere else.

The CHAIRMAN thanked Mr. Drake for his encouraging remarks, and said that in the matter of economy it had been the object of the Directors to keep down expenses as much as possible. The compliment paid to their manager and engineer by Mr. Middleton was thoroughly deserved. They had been endeavouring to encourage their mid-day traffic, from which they hoped to derive considerable benefit. Their short distance traffic—mostly penny fares—had resulted in a considerably increased income, but the average return per passenger was slightly reduced. As regarded the fees of the Directors, he could only say that if they were not worthy of their remuneration, they would be glad to retire in favour of others who would do their work for less. He objected, however, in the interests of the shareholders to any reduction of the Directors' fees.

The resolution was then put to the meeting and carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. HEWETT, dividends at the rate of 5 per cent. on the preference shares, and of § per cent. on the Consolidated Ordinary Stock, were declared.

The CHAIRMAN proposed and a SHAREHOLDER seconded, the re-election of Mr. C. S. Grenfell and E. Tate to their seats at the Board.

The motion was carried *nem. con.*

On the motion of Mr. MIDDLETON, seconded by a SHAREHOLDER, the auditor—Mr. Henry Bishop, of the firm of Messrs. Turquand, Youngs, Weise, Bishop, and Clarke—was unanimously re-appointed.

At an extraordinary meeting held subsequently, a resolution for the conversion into Consolidated Ordinary Stock of the remaining 3,000 ordinary shares already issued was passed unanimously.

Mr. DRAKE proposed a vote of thanks to the Chairman and Directors, which ended the proceedings.

General Electric Power and Traction Company (Limited).

The ordinary general meeting of the shareholders of this Company was held on Tuesday at Winchester House. Mr. James Pender presided.

The SECRETARY (Mr. J. Payne) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the proceedings of our meeting to-day will only be of a formal character. As you will have seen from the circular which we issued on the 27th inst., this meeting will, we propose, be adjourned to February 14th, owing to the illness of our chairman, Lord Albemarle, and also to the illness of Lord Egerton of Tatton. I am told by the Secretary that the report and balance-sheet will be sent out next Friday night. I now beg to move that this meeting be adjourned to the date mentioned.

Mr. ENGLISH: I will second that resolution with pleasure.

A SHAREHOLDER expressed the hope that the balance-sheet and profit and loss account, when received by the shareholders, would be found to be set out a little more fully than they were last year. It was, he said so summarised then, especially the items in the profit and loss account that many of the shareholders were dissatisfied with it.

The CHAIRMAN: The accounts have been thoroughly gone into by the auditors. As you will readily understand, the auditors have had a great deal of trouble and difficulty in the compilation of the accounts. As you know, we lost our first managing director; then our first secretary was unfortunately drowned, whilst his successor went out of his mind. Altogether we have had a series of difficulties to contend with. The auditors have made out a very full balance-sheet.

The SECRETARY: The auditors, in addition to their report, will send out a very elaborate statement, which will be of very great interest to the shareholders.

A SHAREHOLDER: If the chairman is still ill on February 14th will the meeting again be adjourned?

The CHAIRMAN: I really do not know. I do not think so; but I consider it would be very much better to have the chairman present at the general meeting.

Another SHAREHOLDER asked the reason why Mr. Paxman left the Board?

The CHAIRMAN: I really cannot give you any idea, but I think the days on which the Board meetings were held were very inconvenient to him. He is a very busy man.

The SHAREHOLDER: Does he still hold any shares in the Company?

The CHAIRMAN: I cannot tell you.

The SECRETARY: He still holds the same amount in the Company as he did last year.

The CHAIRMAN: Mr. Paxman never told me the reason for his leaving, except on one occasion he said that he found it extremely difficult to attend the Board meetings.

The resolution for the adjournment of the meeting was then put and carried unanimously, and the proceedings terminated.

Giant's Causeway and Portrush Electric Tramway Company.

The half-yearly general meeting of this Company was held on Saturday last at the offices of the Company, Portrush. Dr. Anthony Traill, J.P., F.T.C.D., presided.

The CHAIRMAN, in moving that the Directors' report be adopted, said that the shareholders had all received a copy of the report, and therefore there was little left for him to say except to regret, on the one hand, the diminution in the receipts for the past year which the report disclosed; and, on the other, to congratulate the shareholders upon the fact that, notwithstanding this reduction in their receipts, there was still an increase in the total balance. This had been chiefly brought about by considerable reduction on the expenditure side of the account. He regretted being unable to announce a dividend on this occasion.

Mr. J. STEWART MOORE was re-elected Director of the Company, and a vote of thanks to the Chairman and Directors brought the meeting to a close.

The report of the Directors states that there has been a diminution in the receipts under every head during the past year, as compared with those of the year 1891, though the total is still in excess of that of the year 1890. In passenger traffic there has been a falling off in the number to the extent of 1,591 first-class and 5,137 third-class passengers, making a total of 84,970, compared with 91,698 in 1891 and 82,802 in 1890. The receipts have consequently fallen to £2,663. 0s. 5d., as compared with £2,830. 4s. 2d. in 1891 and £2,579. 19s. 5d. in 1890. The goods and mineral traffic fell to 136 tons from 181 tons in 1891, and 316 tons in 1890 while the receipts under this head have fallen from £29. 1s. 5d. to £17. 7s. during the year. As this traffic was a serious cause of loss in past years, this diminution is not to be regretted. The miscellaneous receipts and those for parcels have diminished from £31. 9s. to £24. 8s. 6d., so that the total recipts from revenue account have been £2,704. 15s. 11d., as against £2,895. 14s. 7d. in 1891, and £2,698. 15s. 4d. in 1890. On the other hand, there has been a considerable reduction on the expenditure side of the account, which shows a total of £1,720. 18s. 10d., as against £1,945. 6s. 6d. in 1891, and £1,687 12s. in 1890. There is consequently a credit balance on the result of the year's working of £983. 17s. 1d., as against £950. 8s. 1d. in 1891, and £1,011. 3s. 4d. in 1890. The past year has therefore fully maintained the successful turn in the state of the finances of the Company which took place in 1890 and 1891, the corresponding credit in 1889 having been only £381. 18s. 7d. The net result of the year has, on the whole been satisfactory, though no dividend can yet be announced.

Elmore's French Patent Copper Depositing Company (Limited).

An extraordinary general meeting of this Company was held on Wednesday at the Cannon-street Hotel, E.C., for the purpose of submitting a resolution giving the Directors power to borrow, for carrying on the Company's business, a total amount not exceeding at any time the issued capital of the Company.

Major CHARLES JONES presided, and in the course of his remarks said that at the general meeting held in April last it was decided, on the recommendation of the Board, to increase the nominal capital of the Company by the creation of 100,000 preference shares of £2 each, and power was taken to issue 60,000 of these shares so as to raise £120,000 additional working capital, which was considered necessary to meet the liabilities of the Company, and to enable the management to push on the manu-

Hosted by Google

facture on the large scale for which the works at Dives have been erected. Had that capital been fully subscribed they would have proved months ago, not only that the Elmore process is a commercial success, but also that it is a financial success. Unfortunately through the delay of the English Elmore Company at Leeds to make their business a financial success, confidence in the Elmore affairs has been shaken, and consequently their Preference issue was not responded to sufficiently to enable them to carry out their programme. They had, however, been able to carry on the work at Dives for some months past, regularly and satisfactorily turning out a considerable amount of goods. And further, they had substantiated every statement that M. Secrétan had ever made as to the quality of the products, the cost of manufacture, and the selling prices that can be realised. In a recent circular to the shareholders, the Directors informed them that they had sold the pan license, which they had done and had received the money, and also that they had made a contract with substantial persons for placing the £50,000 First Mortgage Debentures then proposed to be issued. Unfortunately they were misled, and these persons had failed to carry out their agreement, thus placing the Company in a position of great difficulty. Their only remedy was an action at law for specific damages. Therefore they must either raise more capital by some such scheme as they were going to lay before the shareholders; they must sell the Company outright; or they must reconstruct. They had received from business men in France, through M. Secrétan, a proposal for the purchase of the Company, for cash, shares, and debentures, by a new company to be registered in France, and the raising of £60,000 additional working capital. He need not go into the details of this offer, as it was not accepted. M. Secrétan says that if he is given a sum of £30,000 he will, in six weeks' time, be producing and selling 20 tons per week of tubes. This output is sufficient to show a considerable profit. To raise this money, and to provide for accrued liabilities in England, a scheme has been proposed by which Six per Cent. First Mortgage Debenture Stock to the amount of £100,000, redeemable in five years at £105, would be issued. The holders of the existing £50,000 First Mortgage Debenture Stock would exchange their stock either for Preference shares or new Debenture Stock. Their English creditors would be asked to take preference shares in payment of their debts, and the remainder of the new debentures would be taken up by the present shareholders for cash, thus providing the additional capital we require. It was only by some sacrifice on the part of all concerned that they could hope to save the ship. A large part of the present Debenture Stock holders had already consented to exchange their stock for preference shares. The security was good and ample. He then moved:

"*That the Directors be empowered to borrow for the purposes of the Company's business a total amount not exceeding at any time the subscribed capital of the Company.*"

Sir JAS. MACKENZIE seconded the resolution.

M. SECRÉTAN went into figures regarding the immense profits to follow some day, but our readers will be able to gather the purport of these calculations from a perusal of previous reports.

Mr. BODDINGTON (the legal adviser of the Company in Paris) followed with a flowery description of what the Company were doing and were likely to do.

In reply to Dr. Hedley, Mr. F. L. RAWSON said he had spent considerable time in going into the statements made by the French Company, and he found that there had been no mis-statements of any material character. One or two anticipations had not been carried out, but that was because they had not had sufficient working capital.

Mr. SAUNDERS inquired what probability there was of obtaining money at 6 per cent., seeing that the proposal to raise money at 10 per cent. had not been successful?

The CHAIRMAN pointed out that they were now offering Debentures with the security of all the Company's assets, whereas the other issue was only Preferred shares.

Mr. GLADSTONE asked whether the process sold by the Elmore Company was complete?

M. SECRÉTAN replied that the process, as handed over to him, was capable of making, and did make, tubes. He, however, had modified it and added to it, so as to make the product such as no other manufacture could compare with.

Mr. SIMPSON (a member of the committee of shareholders recently appointed) quoted figures to show that the whole of the capital already supplied to the Dire tors had been legitimately spent.

Ultimately the resolution was carried unanimously.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

BAILY, GRUNDY AND BARRETT (LIMITED).—This Company was registered on January 18, 1893, with a capital of £10,000 in £5 shares. The objects are to take over the business carried on by Robert M. Baily, at No. 2, St. Mary's-passage and Magdalen-street, Cambridge, as electricians, mechanical engineers, and manufacturers, workers, and dealers in electricity, motive power, and light, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, supply, accumulation, distribution, and employment of electricity, and to acquire the right to use or manufacture and put up telephones, telegraphs, and other electrical apparatus. The subscribers are—

	Shares.
Arthur Barrett, St. Mary's-passage, Cambridge, electrical engineer ...	240
Edwin Barrett, 30, Market-place, Cambridge	80
William E. Lilley, 12, Market-street, Cambridge.....	160
John L Smith, 19, Parkside, Cambridge	60
Samuel R. Ginn, Cambridge	60
William J. Crampton, St. Mary's-passage, Cambridge, electrical engineer	1
George A. Matthew, Cambridge, electrical engineer	1

DYNEVOR SPELTER COMPANY (LIMITED).—Capital, £20,000, in £50 shares. Objects: To manufacture and deal in spelter, lead chloride of zinc, zinc oxide, zinc galvanising, copper, &c.

EGGLESCLIFFE IRON COMPANY (LIMITED).—This Company was registered on January 24, 1893, with a capital of £27,000, in £10 shares, to carry on the business of mechanical and electrical engineers, electricians, &c., at the Egglescliffe Foundry, near Stockton-on-Tees.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—The annual return of this Corporation, made up to December 30, 1892, has been filed. The nominal share capital now consists of £750,000, divided into 100 founders' shares of £10 each, 62,400 ordinary shares of £10 each, and 12,500 preference shares of £10 each. Of these, 100 founders, 49,900 ordinary, and 2,926 preference shares have been taken up, of which 4,900 ordinary shares have been issued as fully paid. Upon the 100 founders', 45,000 ordinary, and 2,926 preference shares the full amounts have been called. The calls paid have realised £465,849. 14s. 11d., while a sum of £10,501. 5s. 1d. is yet in arrears.

GENERAL METALLURGICAL COMPANY (LIMITED).—Capital £5,000, in £1 shares. Objects: To acquire and turn to account certain secret processes for manipulating and blending metals.

ALLCHIN, LINNELL, AND CO. (LIMITED).—Notice is given that a first and final dividend in this liquidation of 1½d. in the pound is payable at the Official Liquidator's office, 33, Carey-street, London, W.C., any day except Saturday.

ART WORKSHOPS (LIMITED).—A winding-up order was made in the Royal Courts of Justice on January 21st.

MACMAHON'S PATENT ELECTRIC CHECK SYSTEM (LIMITED).—A meeting of this Company is to be held at the Salisbury Hotel, Salisbury-square, London, E.C., on March 3rd, at 3 p.m., to receive an account of the winding up.

RICHMOND (SURREY) ELECTRIC LIGHT AND POWER COMPANY (LIMITED.)—The statutory return of this Company, made up to Jan. 19, 1893, has been filed. Only seven shares of a total capital of £50,000, in £5 shares, have been taken up. The full amounts have been called, and all calls (£35) paid.

S. Z. DE FERRANTI (LIMITED).—The annual return of this Company, made up to December 24, 1892, has been filed. The Company has a capital of £100,000, divided into 2,000 £7 per cent. preference, and 8,000 ordinary shares of £10 each, and was registered on June 26, 1890, to carry on the business of electrical and general engineers carried on by Sebastian Z. de Ferranti, Francis Ince, and Charles P. Sparks. The Company acquired the business for £99,930, which was fully satisfied by the allotment of 1,993 fully-paid preference shares of £10 each, and by the allotment of the 8,000 fully-paid ordinary shares of £10 each. At the time of making up all the shares had been taken up, of which seven preference shares have had the full amount called and paid on them, the remainder having been issued as fully paid in accordance with the above agreement.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The annual return of this Company, made up to January 5, 1893, has been filed. Out of a total share capital of £550,000, divided into 60,000 ordinary shares of £5 each, and 50,000 preference shares of £5 each; 55,197 ordinary and 41,008 preference shares have been taken up. Of these shares, 8,564 ordinary and 9,936 preference shares, of a nominal value of £92,500, have been issued as fully paid. Upon 31,072 preference and 9,119 ordinary the full amount has been called, and upon the remaining 37,514 ordinary shares calls amounting to £3. 15s. per share have been made, resulting in the payment of £8334,351. 12s. 6d. (which includes a sum of £180 paid on 60 shares forfeited), and leaving £7,280. 17s. 6d. as yet in arrear.

CITY NOTES, &c.

BUDAPEST.—Messrs. Ganz and Co. are reported to be forming a limited liability company, with a capital of £300,000, to carry on the electric lighting of the town of Budapest, Hungary.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 29nd were £976, as against £823 for the corresponding period of last year, being an increase of £153 The total receipts for half-year amount to £3,954, against £3,328 in the corresponding period of 1892, being an increase of £626.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January amounted to £60,516 and to £63,436 in the corresponding period of 1892

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the

Hosted by Google

month of January, 1893, amounted to £40,040, and to £42,805 in the corresponding period of 1892, or an increase of £235.

FRENCH ELECTRICAL POWER STORAGE COMPANY (LIMITED).—The creditors of this Company (which has been for some years in liquidation) are notified that a first and final dividend of 0·28f. per cent. is now payable at the office of M. Roucher, 1 bis, Rue Hautefeuille, Paris.

HOPE-JONES ELECTRIC ORGAN COMPANY (LIMITED).—This Company are inviting subscriptions for the balance of their Preference shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended January 27, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,648.

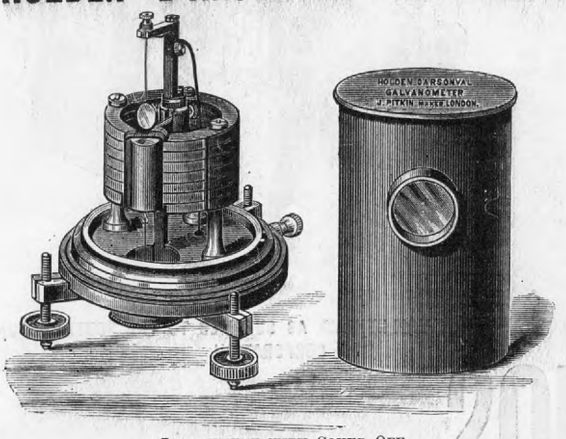
HOLDEN D'ARSONVAL UNIVERSAL DEAD BEAT REFLECTING GALVANOMETER.



INSTRUMENT WITH COVER OFF.

As supplied complete with Three Coils, Shunts, Resistances, and Self-locking Key, it is

The Best Galvanometer for Zero Testing.
The Best Galvanometer for Direct Measurements.
The Best Galvanometer for Measuring Large or Small Currents by the Shunt Method, from 1 to 1,000 Amperes.
The Best Galvanometer for Measuring E.M.F. from ·001 to 100 Volts.

Prof. W. AYRTON, Pres. I.E.E., speaking at the Institution on 26th Nov., 1891, said:—"*The deflection is larger than we have obtained with any other D'Arsonval of anything like the same size. . . . . Many times as sensitive as the Carpentier pattern for the same periodic time and resistance of coil. . . . . The method of construction has the great convenience that the coil, with its top and bottom supports, can be at once bodily withdrawn. . . . . .*"

As supplied to H.M. Govt.; The Central Institution; City Guilds; Electrical School, Chatham; R.A. College; Yorkshire College, &c.; and to Prof. Ayrton, F.R.S.; Prof. Fleming, F.R.S.; Sir T. Bazley, Mr. J. W. Swan, and many others.

Circulars, with all information, from the SOLE MANUFACTURER,

Mr. J. PITKIN, 56, RED LION STREET, CLERKENWELL, E.C.

Maker of Capt. HOLDEN'S CHRONOGRAPHS, FIRING KEYS & ELECTRICAL MEASURING INSTRUMENTS, particulars of which will be sent on application.

STREET LIGHTING OF CITY OF LONDONDERRY BY ELECTRICITY.

THE CORPORATION of the CITY of LONDONDERRY invites TENDERS for the SUPPLY and ERECTION of certain Steam Boilers, Steam Engines, Condensers, Steam and Water Pipes, Water Tanks, Electrical Machinery and Apparatus, Arc Lamps, Lamp Pillars, Underground Mains, &c., for Lighting of Streets by Electricity.

Copies of Plans and Specifications, prepared by Mr. Henry W. Blake, Engineer, can be obtained from the undersigned, at the Guildhall, Londonderry, on and after 10th instant, on payment of £1. 1s., which will be returned on receipt of a bona fide Tender.

Tenders will be received for the whole or any item of the Specification.

Tenders to be delivered to the undersigned, at the Guildhall, Londonderry, not later than 1st March next.

The Corporation does not bind itself to accept the lowest or any Tender.

By order,

R. N. CHAMBERS, Town Clerk.

Guildhall, Londonderry, 2nd February, 1893.

GREAT WESTERN RAILWAY.

The DIRECTORS of this Company are prepared to receive TENDERS for the SUPPLY of about:—

60,000 CARBONS for ELECTRIC LIGHTING.

Specification with Forms of Tender (upon which alone Tenders can be received), may be obtained of the Secretary, at the Paddington Station, or of the Stores Superintendent, at Swindon.

Tenders, addressed to the undersigned, and marked outside "Tender for Carbons," will be received on or before Wednesday, the 1st proximo.

The Directors do not bind themselves to accept the lowest or any Tender.

G. K. MILLS, Secretary.

Paddington Station, London, 9th February, 1893.

COUNTY BOROUGH OF BOLTON.

The BOLTON CORPORATION are prepared to APPOINT an ELECTRICAL ENGINEER to have charge of the construction of the works of electric installation intended to be carried out for the Borough and to have the management of such works when completed. He will be required to devote the whole of his time to the duties of the appointment.

Salary to commence with £200 per annum.

Applications, stating age and experience, together with testimonials, to be delivered to the undersigned on or before the 22nd February, 1893.

By order,

R. G. HINNELL, Town Clerk.

Town Hall, Bolton, 1st February, 1893.

YOUNG ELECTRICAL ENGINEER WANTED, with about two years' experience; also VACANCY for IMPROVER.—Write and then call before 10 o'clock, GILBERT AND CO., 35, High-street, Kensington.

WANTED, a First-class WIREMAN. Preference will be given to a man capable of taking charge of an Electric Light Installation of 300 Lights. Good character and references indispensable. State wages required. Only experienced men need apply to "ELECTRICITY," care of Cox and Sharland, Printers and Stationers, Southampton.

ADVERTISER (26), seeks EMPLOYMENT as ASSISTANT ELECTRICIAN, or Dynamo Attendant, Arc and Incandescent Lighting and Accumulators. Understands Crossley's gas engines. Late assistant at well-known London private installation.—Apply, Box 1170, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER, with eight years' practical experience with leading firm, seeks RESPONSIBLE POSITION in Central Station or Electrical Business, London or Provinces.—1166, *Electrician* Office, Salisbury-court, Fleet-street, London, E.C.

ELECTRICAL ENGINEERS.—WANTED to APPRENTICE a YOUTH, aged 16, in a good firm. Moderate Premium.—"H. P.," 74, Albert-road, Hoe-street, Walthamstow.

ELECTRICIAN (age 20) desires RE-ENGAGEMENT, Meter Department or Central Station, four years' experience high and low tension. Good references.—"W. S.," 135, High-street, Margate.

MECHANICAL ENGINEER with some electrical knowledge desires SITUATION in works or Central Station (preferred). Wages no object.—"J. W. G.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

TO ELECTRICAL and other ENGINEERS.—WANTED to place a premiumed PUPIL, working with a good go-ahead firm.—Lett ers to "GUARDIAN," care of J. W. Vickers, 5, Nicholas-lane, E.C.

WIREMAN (22), good references, wants SITUATION.—Apply "W. C. B.," Clovelly, Vicarage-road, Leyton, Essex.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

TRADE MARK.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 769.—Vol. XXX. FRIDAY, FEBRUARY 10, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

A brief account of the Liverpool Overhead Railway will be found in another column, together with a few illustrations which, although engraved some time ago, we have, by special request, refrained from publishing until after the opening ceremony. Many columns might be filled with a description of the construction of the line, but this is outside our province. The electrical arrangements, as far as locomotion is concerned, appear to be admirably simple. The use of motors on each carriage, instead of on a separate locomotive, is undoubtedly the ideal method, and the supposed need for concentrating otherwise useless weight on the driving wheels to give the necessary adhesion will, we hope, disappear as completely as the ancient idea that racks were necessary for this purpose in ordinary railway work. It may be that a separate motor will be wanted for each wheel in some cases.

Mr. A. Wright has lost no time in putting into practice the method of charging for electrical supply which he described in our Correspondence Columns some six weeks ago, and the Brighton Corporation are now charging only half-price, or 3½d. per supply unit for all consumption in excess of two hours per day for each 8-c.p. lamp fixed. A recording instrument is placed by the Corporation on the consumers' premises. The readings of this instrument are to be averaged in the three darkest months of each half-year, and this average will be taken as indicating the number of 8-c.p. lamps demanded, also the number of units to be consumed in each half-year before half-price begins to be charged. The total number of hours between sunset and 8 p.m. throughout the year may be reckoned up laboriously from an almanack, but it is evident that in any part of the world the average time of sunset is 6 o'clock, and there must be an average of two hours between sunset and 8 p.m., making about 730 hours in the year. A 32 watt lamp for 730 hours at 7d. comes to 13s. 8½d., and this average must be attained before the price begins to fall below 7d. The average revenue per lamp of the St. James's and Pall Mall Company for the last half-year was 13s. 11d., and this figure will doubtless stand near the top of the list when the accounts of the companies are published. In order to reduce the price to 6d. per unit, each lamp must be burned from sunset till 8.45 p.m., and to reach 5d. it must not be extinguished until 10.40 p.m.

Torn by tar distillers, coaxed by coke merchants, and devoured by dealers in ammonia, the Gaslight and Coke Company find that they are unable to reduce the price of gas to the old figure; and instead, as had been expected, of being able to add some £30,000 or £40,000 to the reserve, they have only been able to make both ends meet, and to carry forward £500. They are evidently just beginning to feel the competition of electric lighting; it is very trifling at present, but just enough to give a bitter flavour to that part of Colonel Makins's speech, at the recent meeting of this Company, which dealt with electrical matters. It was, perhaps, as well that the St. James' and Pall Mall Company had not at that time declared a voluntary reduction of over 14 per cent. in their price, viz., from 7d. to 6d., with a sliding scale discount for large consumers, bringing it down to 5d. in some cases. But this would have been so easily explained, because everybody knows that this is a favoured district, and the members of Clubs in Pall Mall may be found "huddled together in the smoking-room, cursing the electric light for its want of warmth, and bemoaning the departure of gas."
